Detection, recognition, and classification

- Detection = 2-class classification problem
 - Object/class or not object/class
 - E.g., detect all the faces in this image
- Recognition of identity = within-class classification problem
 - Within a given class of objects (e.g., faces, logos), identify the object as one particular member of the class (e.g., Joe's face, Nike logo)
- Recognition of class = among-class classification
 - Which class of things is this: sky, cloud, forest, face, ...

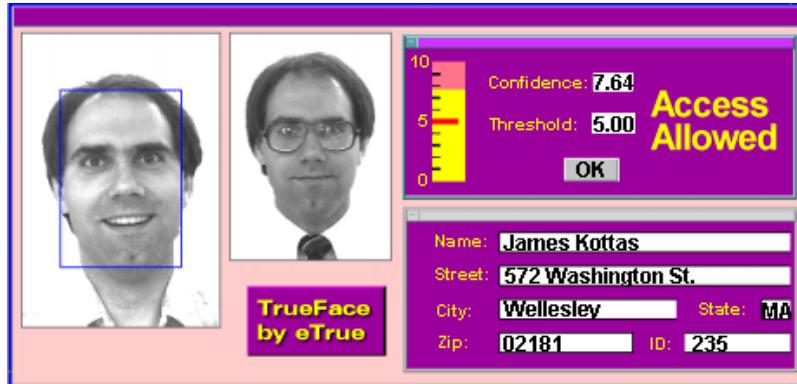

Example: Face detection

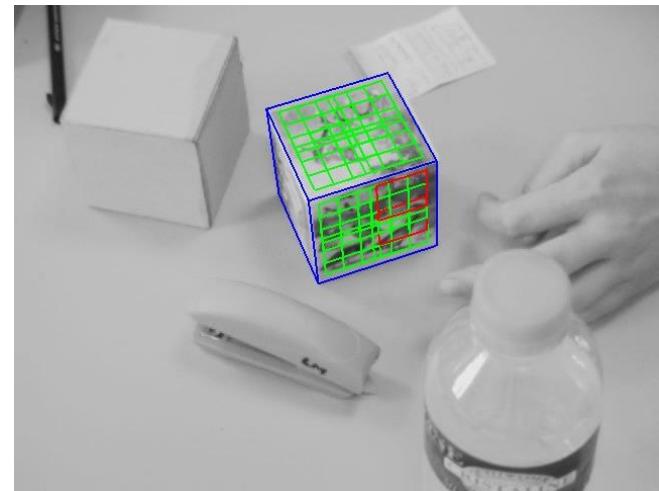

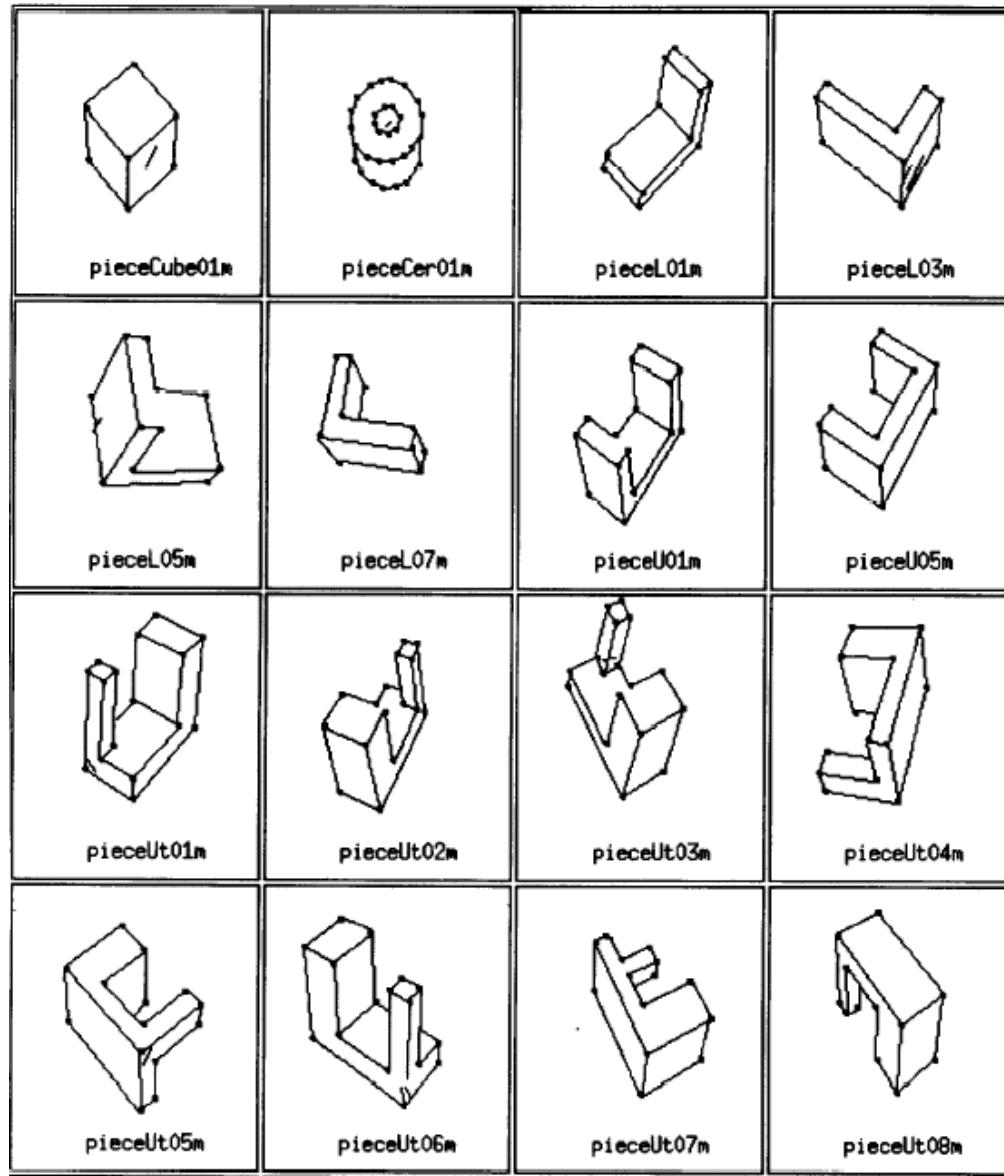

Found Face at [x=108, y=80]
Found Face at [x=76, y=73]
Found Face at [x=257, y=99]
Found Face at [x=154, y=44]
Found Face at [x=211, y=100]
Found Face at [x=147, y=97]

Example: Face recognition

Example: Polyhedral object recognition

Approaches to detection and classification

- There are many approaches to object detection and recognition, depending on how the object is modeled
 - Template-based: Match an image template (or a family of image templates) of the desired object
 - Feature-based: Derive image features and then match with feature model of object
 - ◆ Colors, texture, edges, corners, ...
 - Shape (2D or 3D): Describe (parameterize) the object contour or full shape, and look for that shape in the image
 - And many more...
- In some sense, all these can be viewed as three steps:
 - Modeling the object(s) (“training”)
 - Preprocessing the image (computing features, shape, ...)
 - Classify based on a comparison or match between model and image data

Template matching and classification

- If we want to detect and recognize (classify) objects in images, one simple technique is to use normalized correlation
 - Provides a measure of how well the correlation template matches the image region
 - I.e., “template matching”
- But in general there is not just one template to match
 - E.g., in face recognition – possibly many example templates (different people, expressions, lighting, rotation, scale, ...)
 - A *classifier* takes an input feature set and produces an output class label

Classifiers

- A classifier assigns a label to any new example
 - E.g., the object name
 - Classes: {Joe, Bob, Mary, Fred, Lisa, unknown}
- A two-class classifier is a detector
 - Classes: {face, no face}
- The classifier is trained from a ***training set***
 - Training set: $(x_1, y_1), (x_2, y_2), (x_3, y_3), \dots$
 - x_i – measurements (image, features, histogram, ...)
 - y_i – labels
 - This is typically framed as a **learning** problem
- Outcome: $(i \rightarrow j)$ means outcome i is labeled as j
 - (*Matthew* \rightarrow *Ralph*) – error
 - (*Matthew* \rightarrow *Matthew*) – correct

Training set

- Training set examples:
 - $(\text{image}_1, \text{"Joe"})$, $(\text{image}_2, \text{"Fred"})$, $(\text{image}_3, \text{"Sue"})$, ...
 - $(\text{color}_1, \text{"Face"})$, $(\text{color}_2, \text{"Hair"})$, $(\text{color}_3, \text{"Lips"})$, ...
 - $(\text{template}_1, \text{"eye"})$, $(\text{template}_2, \text{"eye"})$, $(\text{template}_3, \text{"eye"})$, ...
 - Perhaps ***negative*** examples also: $(\text{image}_i, \text{"Not a face"})$...
- We want a rule (function) that does
 - $F(\text{new measurement}) = \text{label}$
...with a low error rate
- Errors
 - False positives: ***Yes*** when the true answer is ***No***
 - False negatives: ***No*** when the true answer is ***Yes***
 - Misclassifications: ***A*** when the true answer is ***B***

Classification errors

- For detection (two-class)

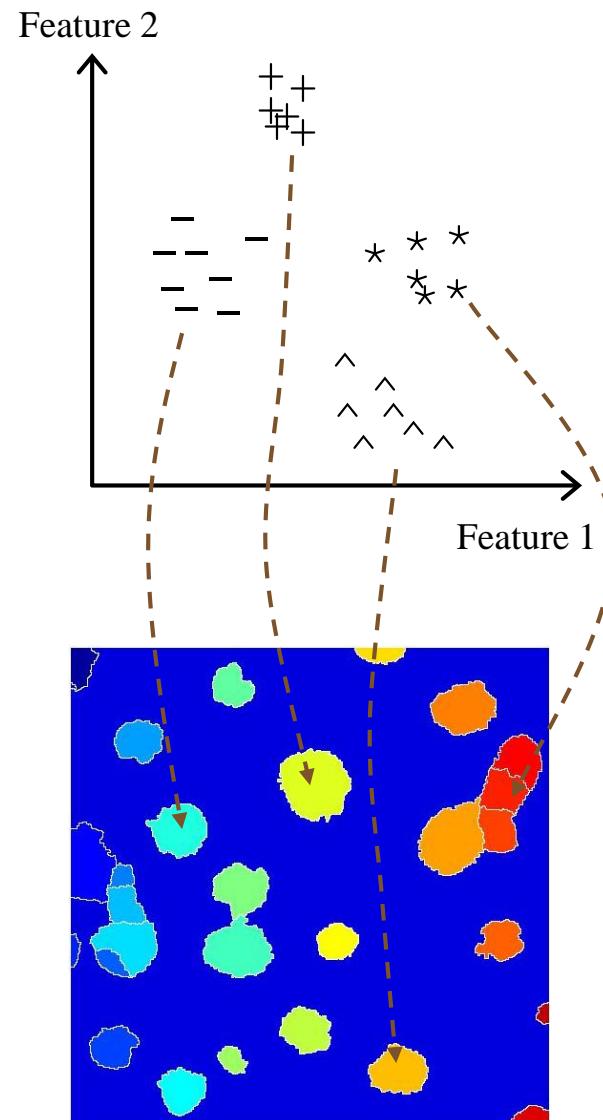

| | Absent (0) | Present (1) |
|------------------|--------------------------------------|--------------------------------------|
| Not detected (0) | True negative ($0 \rightarrow 0$) | False negative ($1 \rightarrow 0$) |
| Detected (1) | False positive ($0 \rightarrow 1$) | True positive ($1 \rightarrow 1$) |

Misclassifications: $(i \rightarrow j)$, where $i \neq j$

Misclassifications = False negatives + False positives

Segmentation and clustering

- Segmentation is about labeling similar pixels as belonging to the same group or segment
 - Pixels that *belong together* = pixels that *cluster*
- Clustering can be done along many dimensions (intensity, color, depth, motion, texture, ...)
 - Individually or combined
- There are some basic clustering methods that do well in certain cases
 - E.g., “k-means clustering”

Clustering/segmenting by k -means

- The “ k -means” algorithm is a fast, simple way to cluster N -dimensional data
 - Given a bunch of data points, group them into k different clusters
 - Each data point is typically a feature vector
 - ◆ But could even be RGB values
- We would like to minimize the *objective function*

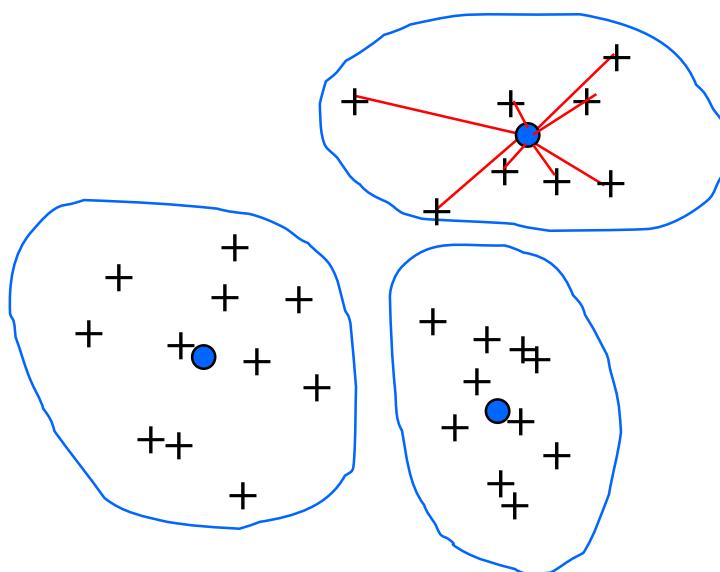

$$\Theta(\text{clusters}, \text{data}) = \sum_{c_i} \sum_{x_j \in \text{clusters}} \sum_{j \in \text{cluster}(i)} (x_j - c_i)^T (x_j - c_i)$$

...but this is too expensive to do for lots of data points!

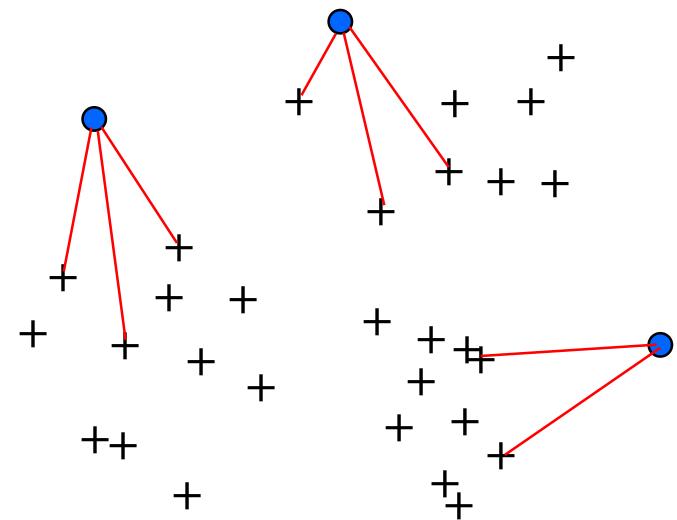

k -means clustering

$$\Theta(\text{clusters}, \text{data}) = \sum_{i \in \text{clusters}} \sum_{j \in \text{cluster}(i)} (x_j - c_i)^T (x_j - c_i)$$

= the sum of the squares of the distances to cluster centers (means)

Data points Cluster centers

The objective function would be larger in this case

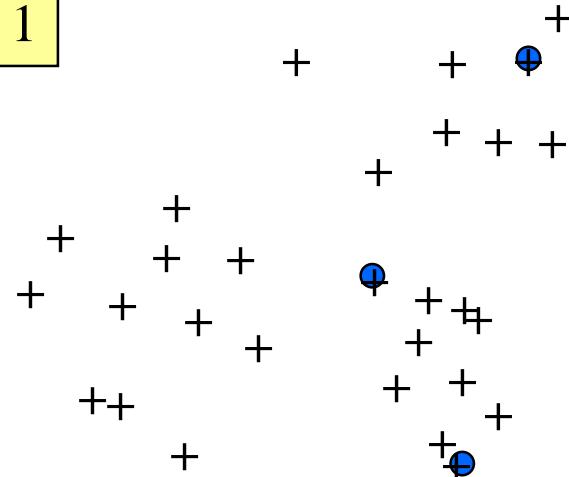

k-means clustering

Algorithm

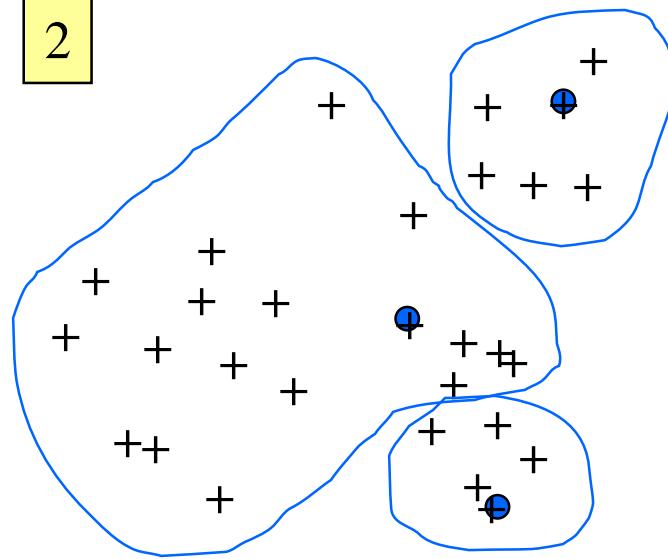

- Randomly choose k data points to be the initial cluster centers
- Iterate until centers are stable:
 - Assign each point to the nearest cluster
 - Recalculate the cluster center (mean)

4

Classification/detection example

Task: Automatically detect abnormal white blood cells

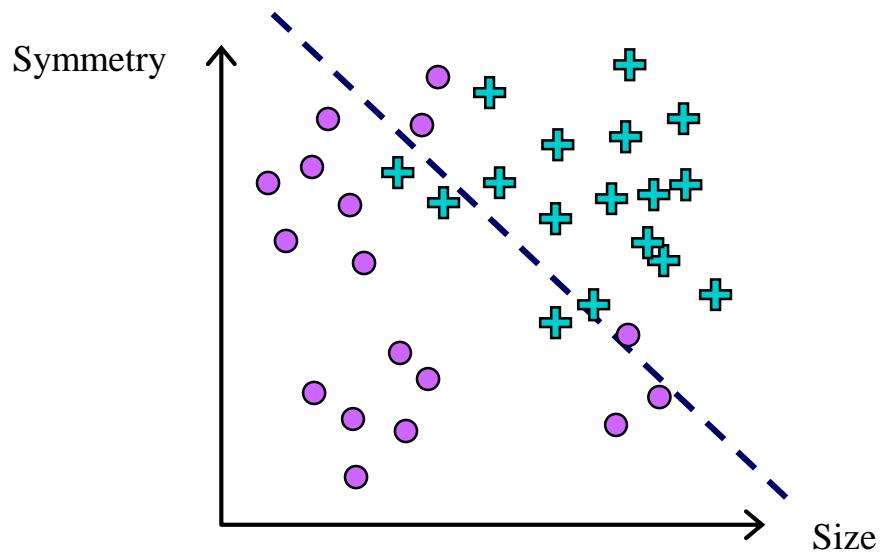

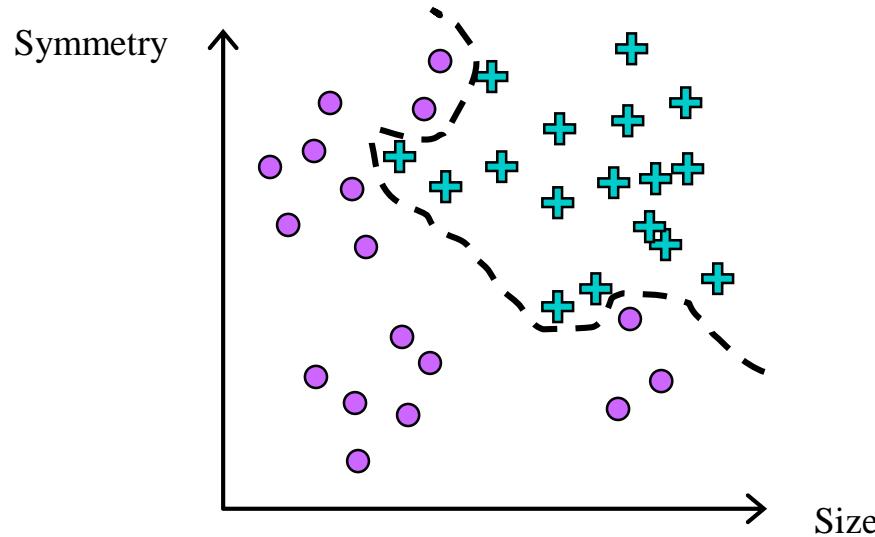

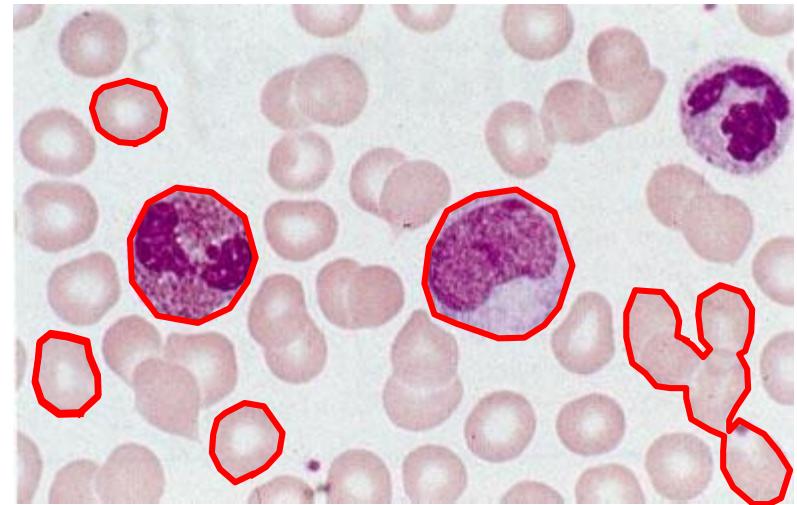

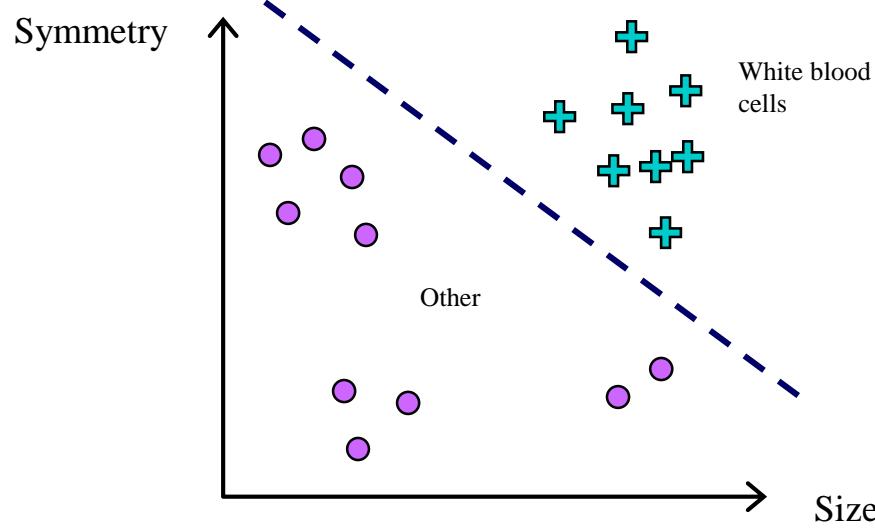

1. Process images to find outlines
2. Count white blood cells
3. Classify abnormal white blood cells

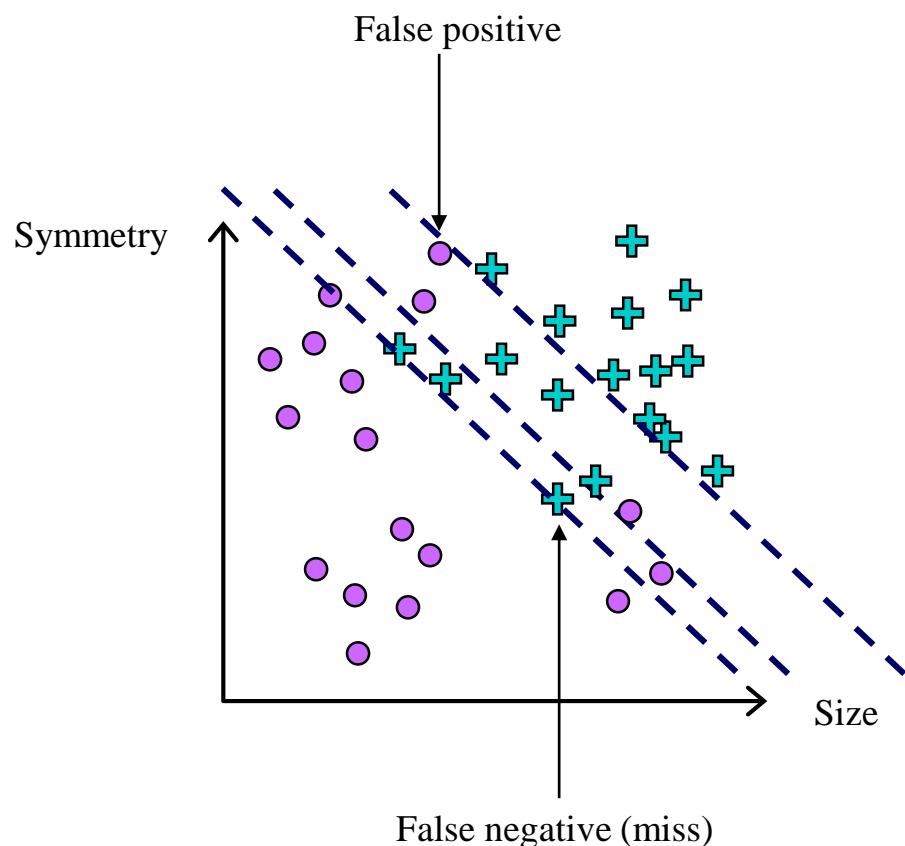

Steps 2 and 3 require *training* – teaching the system how to distinguish between white blood cells and others, and between normal and abnormal white blood cells

It's very important to choose good, discriminating features

Classification/detection example

Where to place the boundary?

We wish to minimize false positives and false negatives

Training vs. Testing

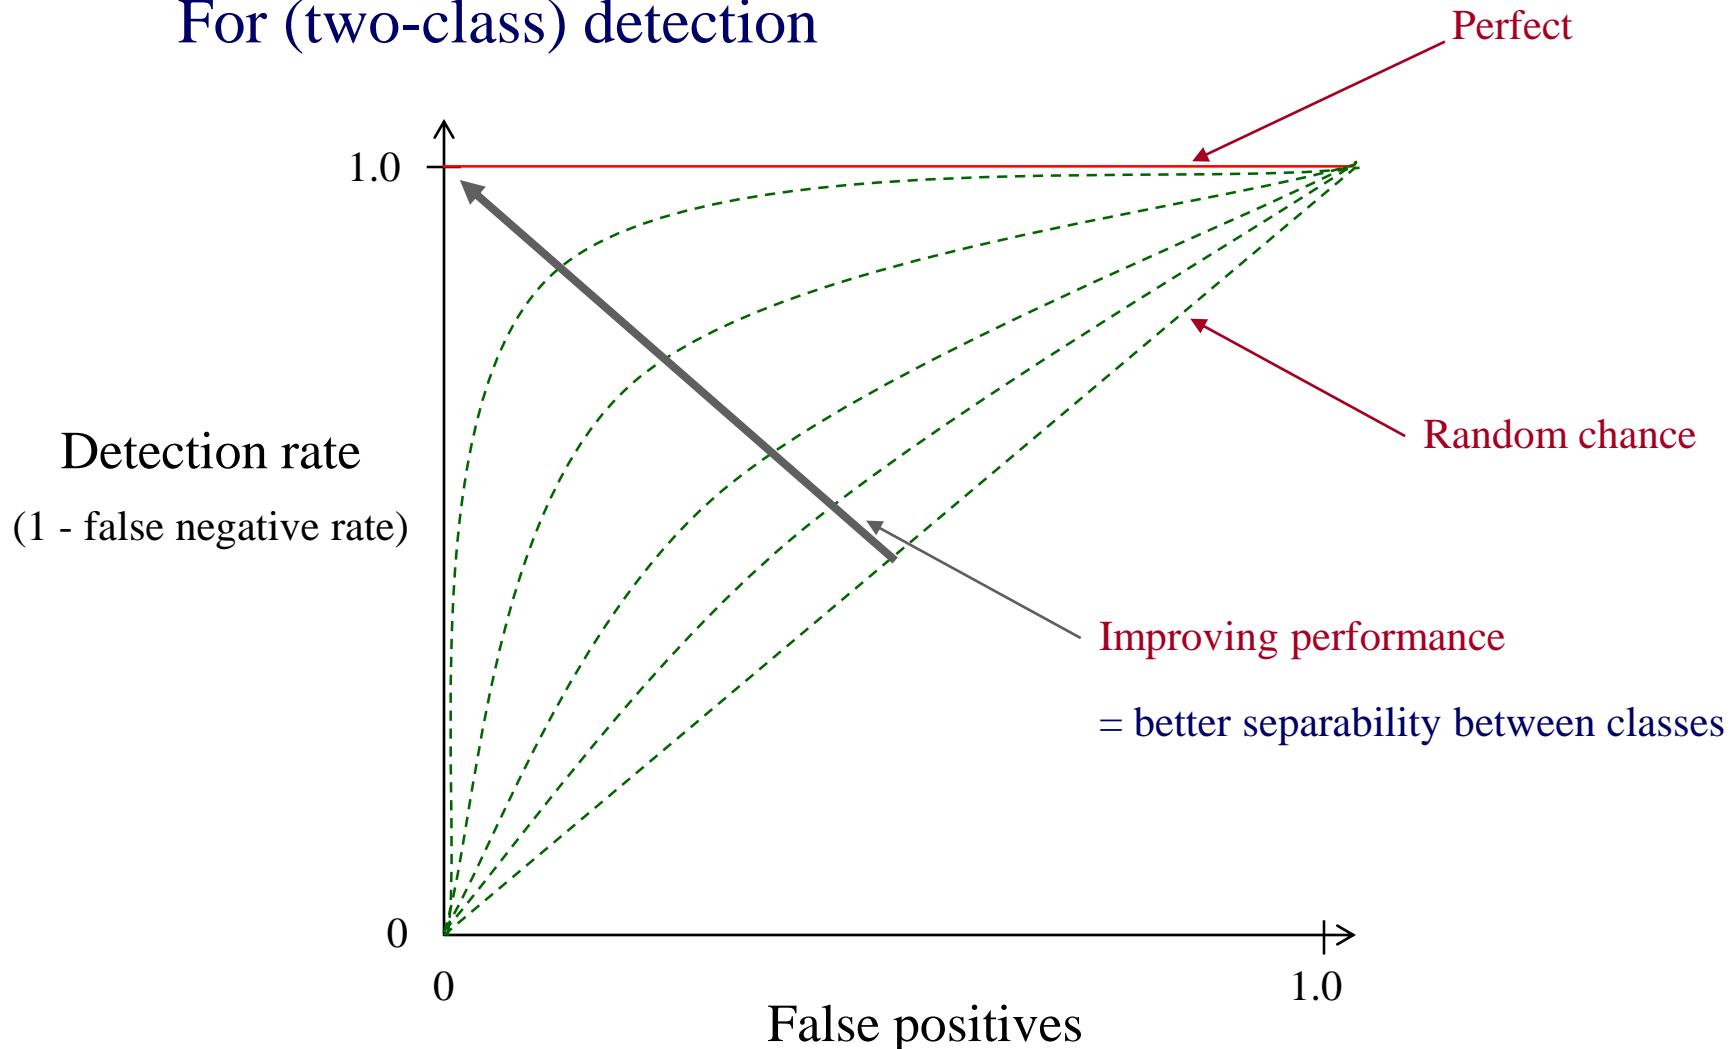

The *training set* (known examples) should be representative of the *testing set* (real data).

Good performance on your training set alone is meaningless...!

In every experiment, keep the *training* and *testing* data separate.

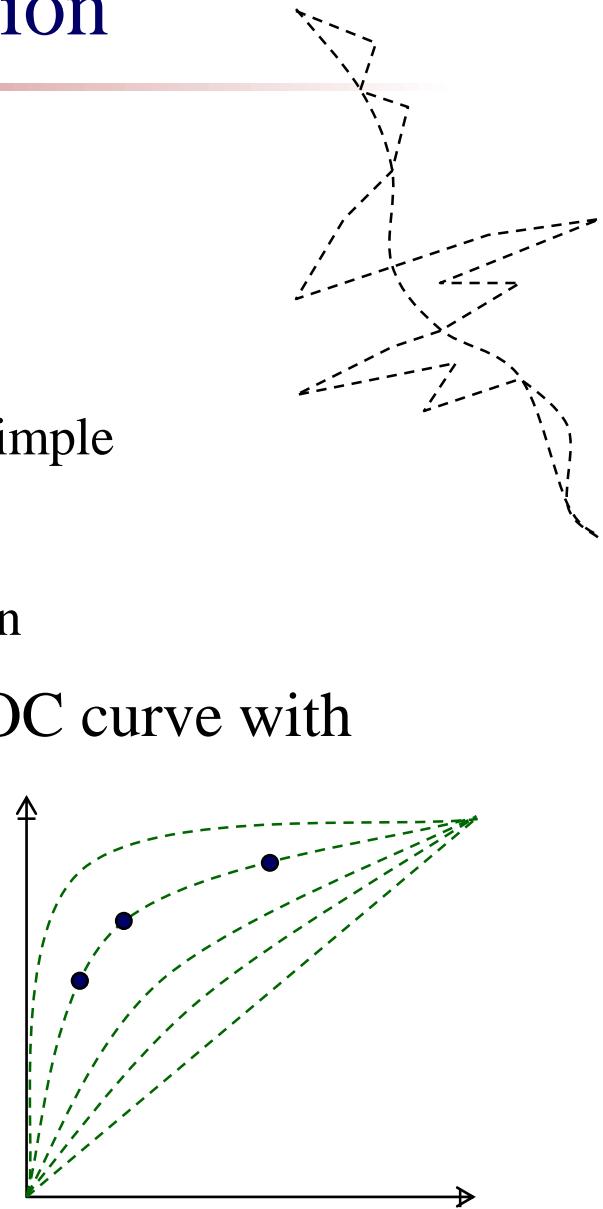

Evaluating performance – the ROC curve

For (two-class) detection

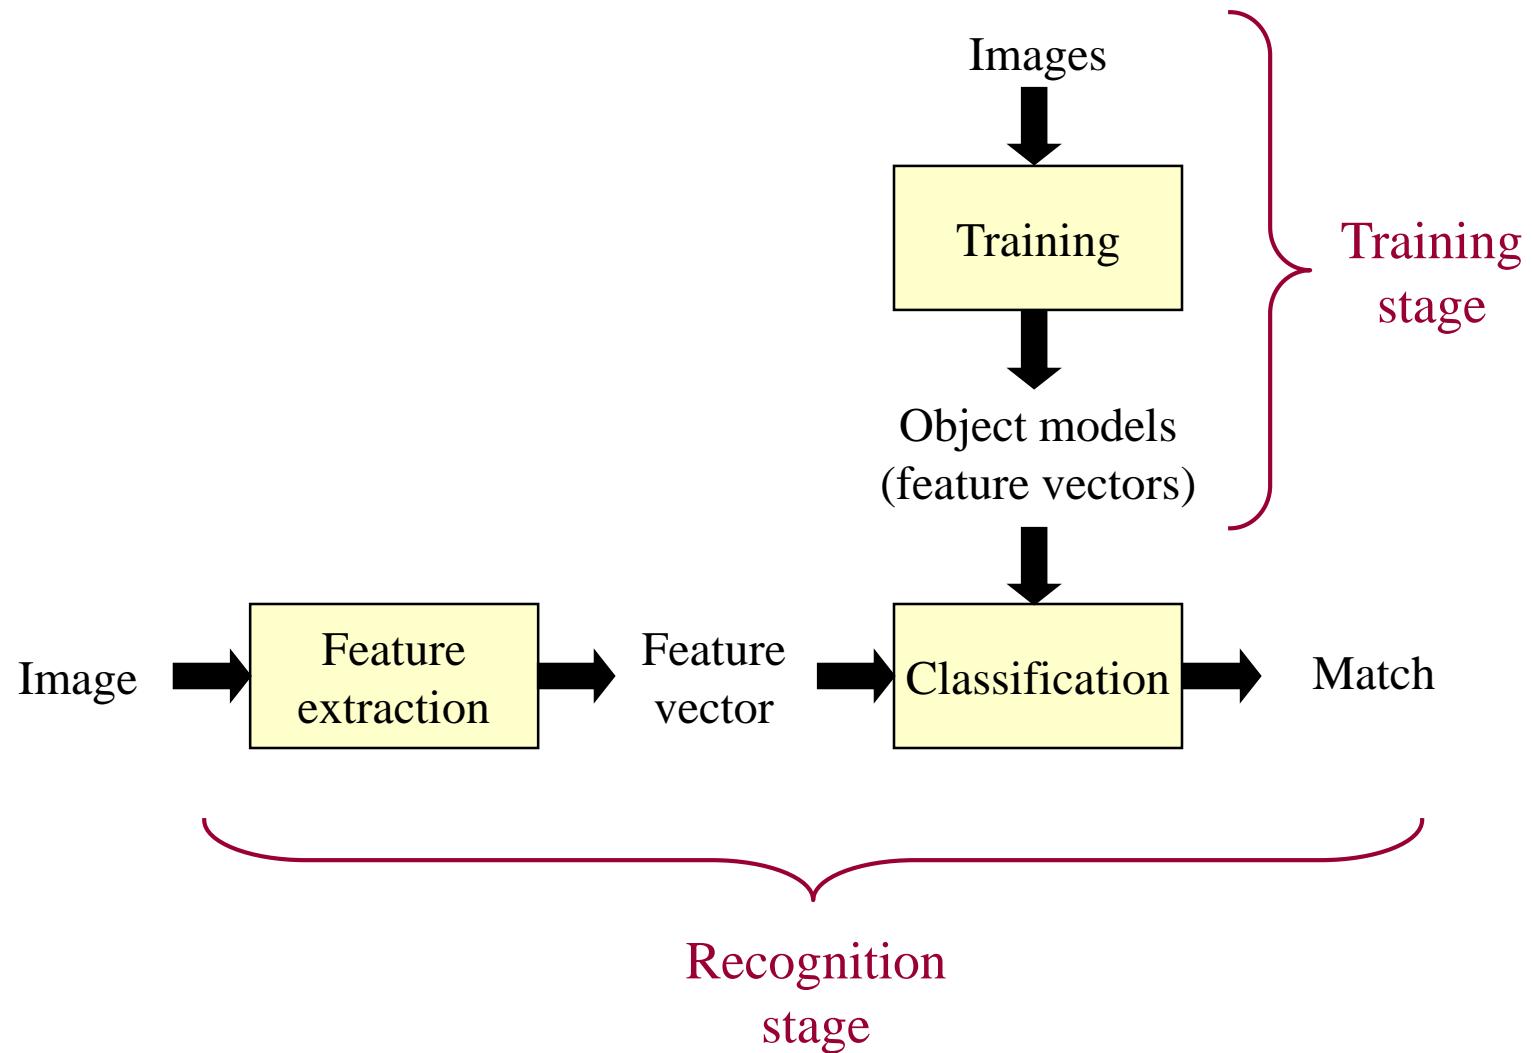

Improving classification/detection

- More training samples
 - So classification strategy is more general
- Don't “overtrain”
 - Don't want to “learn the noise” – keep it simple
- Use better features
 - Good features lead to good class separation
- Don't confuse movement *along* the ROC curve with *improving* the ROC curve

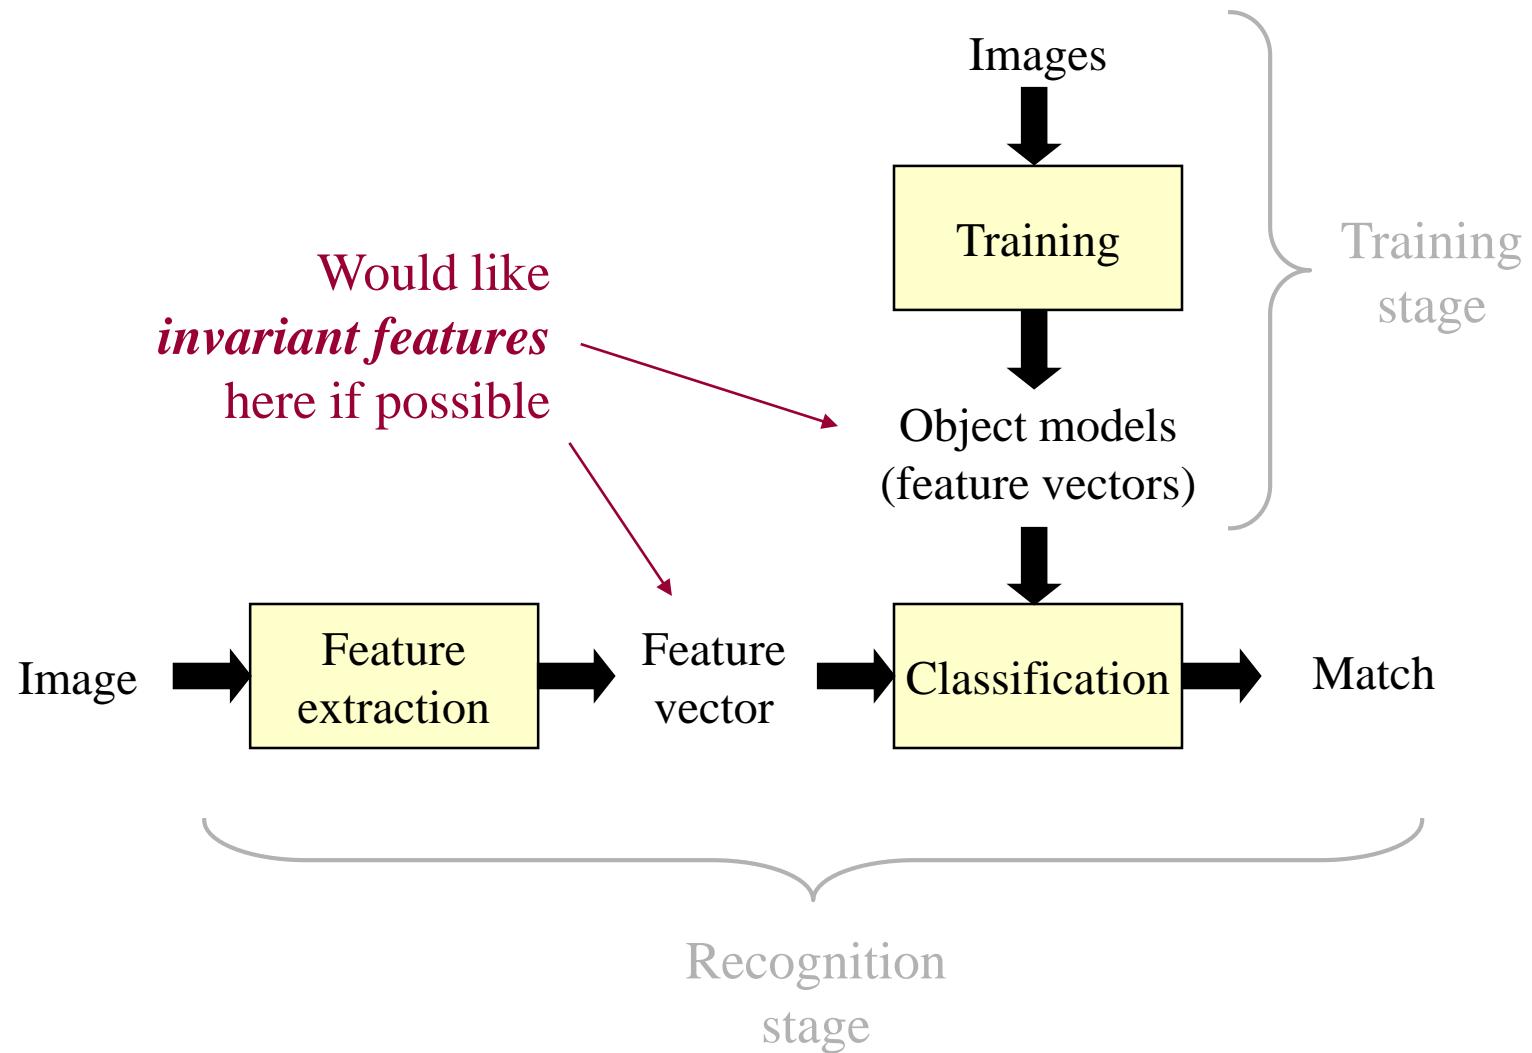

General approach to recognition

Invariant features for recognition

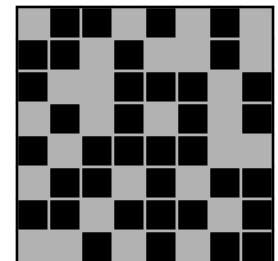

- An *invariant* feature is one that does not change under a certain class of transformations
 - Lengths and angles are invariant under rigid motion
 - Normalized correlation is invariant under scaling of image intensities
 - Brightness/color of a Lambertian surface is invariant under rotation
 - Length and angles *in the image* are **not** invariant under out-of-plane rotation and translation
 - Etc....
- Invariants can be geometric (location, shape) or radiometric (image values)
 - Geometric invariants tend to be much more common and useful

General approach to recognition

Why not this for face recognition/detection?

1. Ahead of time, search over all possible images to see which ones look like my face, and save these
 2. During recognition, see if the input image is one of these
-
- Image space is vastly large
 - 8x8 binary image → 2^{64} image points (distinct images)
 - 1 billion images per second → **600 years**
 - Step #1 would never finish!
 - Not to mention, we'd have to do this for every possible view of my face
 - Range of facial expressions, lighting conditions, poses, etc.

Reminder: Why computer vision is so hard!

These are all images
of Simon's face!

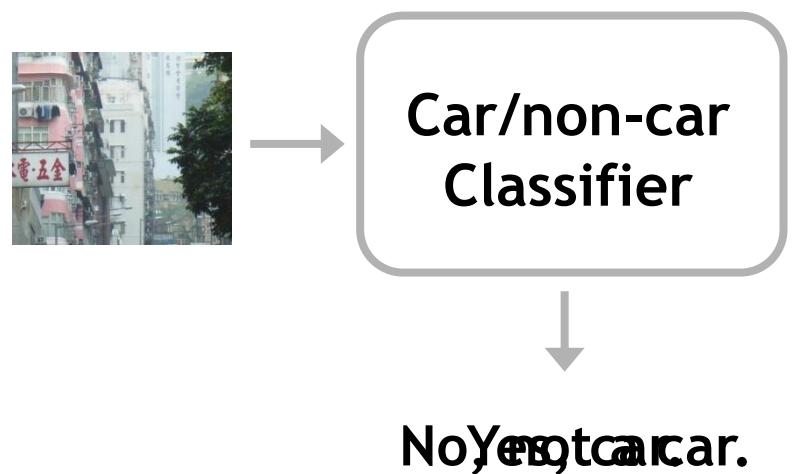

In general, object recognition is difficult because of the immense variability of object appearance. With faces, this is even worse!

How can we reliably detect/recognize Simon???

Scanning windows...

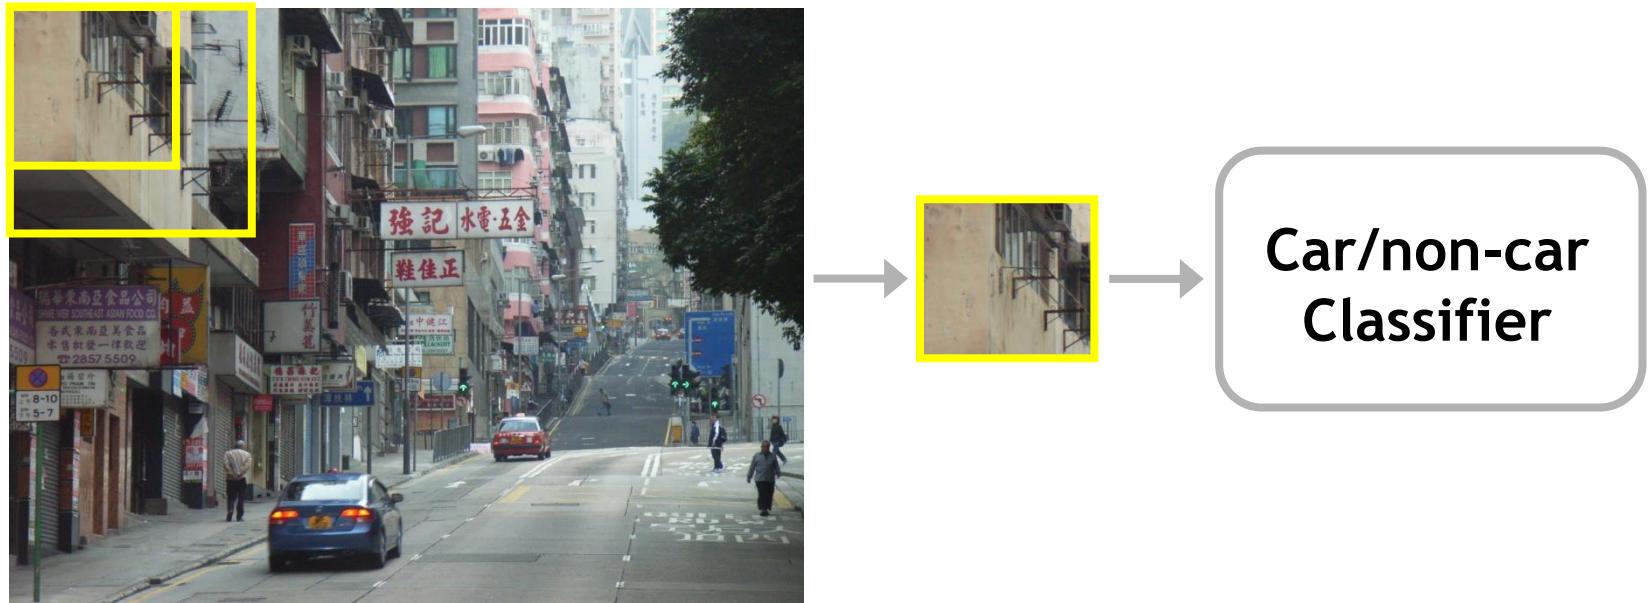

Detection via classification: Main idea

Basic component: a binary classifier

Detection via classification: Main idea

If object may be in a cluttered scene, slide a window around looking for it.

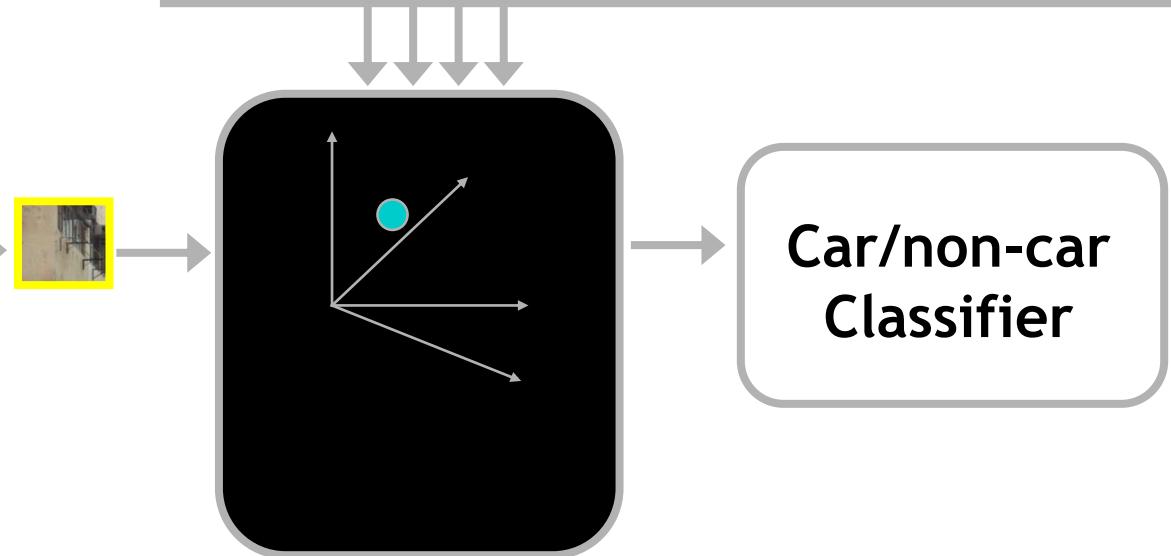

(Essentially, our skin detector was doing this, with a window that was one pixel big.)

Detection via classification: Main idea

Fleshing out this pipeline a bit more, we need to:

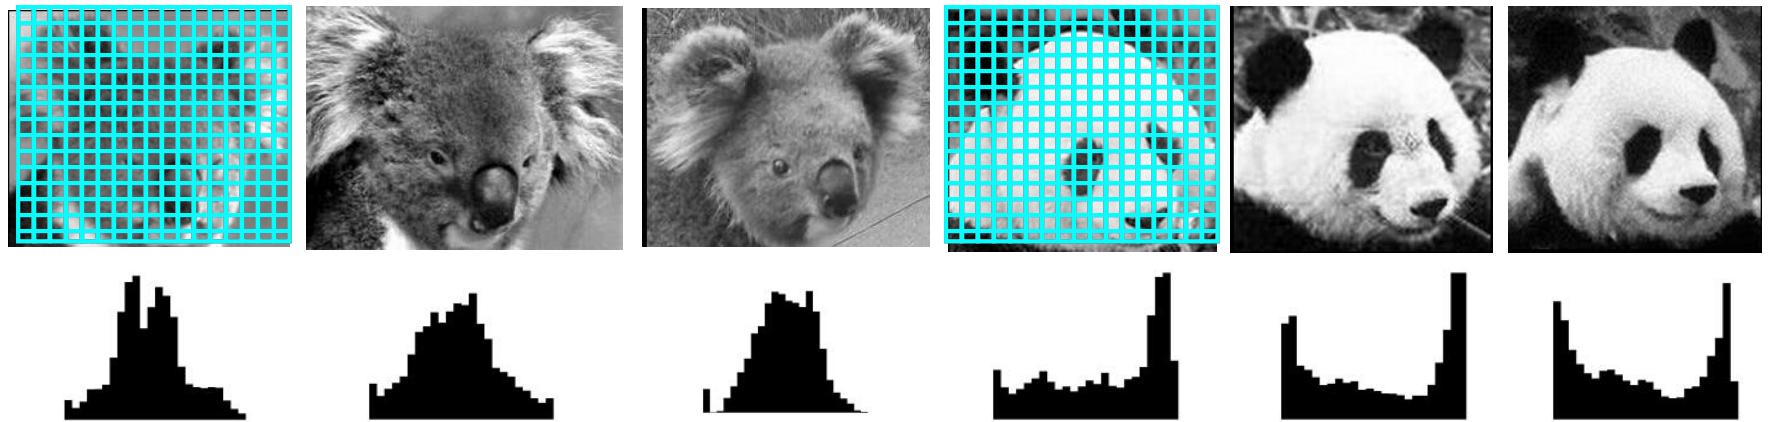

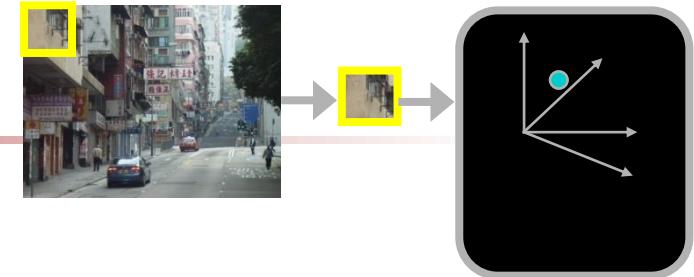

1. Obtain training data
2. Define features
3. Define classifier

Detection via classification: Main idea

- Consider all subwindows in an image
 - Sample at multiple scales and positions (and orientations)
- Make a decision per window:
 - “Does this contain object category X or not?”

Feature extraction: global appearance

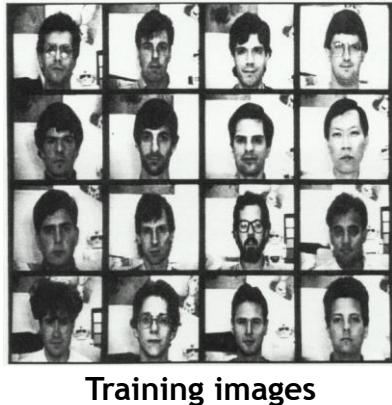

Simple holistic descriptions of image content

- grayscale / color histogram
- vector of pixel intensities

Eigenfaces: global appearance description

An early appearance-based approach to face recognition

Eigenvectors computed
from covariance matrix

Generate low-dimensional representation of appearance with a linear subspace.

\approx

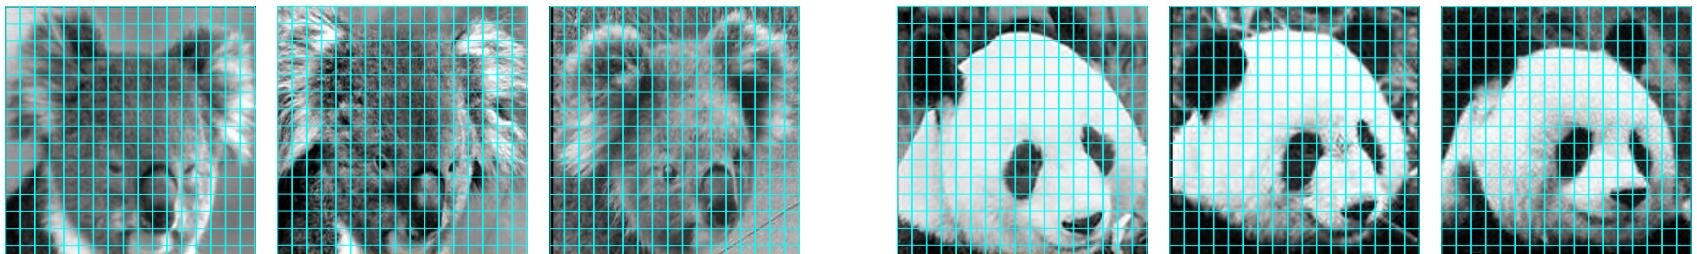

$$\text{Mean} + w_1 \begin{pmatrix} \text{eigenface}_1 \\ \text{eigenface}_1 \\ \vdots \\ \text{eigenface}_1 \end{pmatrix} + w_2 \begin{pmatrix} \text{eigenface}_2 \\ \text{eigenface}_2 \\ \vdots \\ \text{eigenface}_2 \end{pmatrix} + \dots + w_k \begin{pmatrix} \text{eigenface}_k \\ \text{eigenface}_k \\ \vdots \\ \text{eigenface}_k \end{pmatrix}$$

Project new images to “face space”.

Recognition via nearest neighbors in face space

Feature extraction: global appearance

- Pixel-based representations sensitive to small shifts

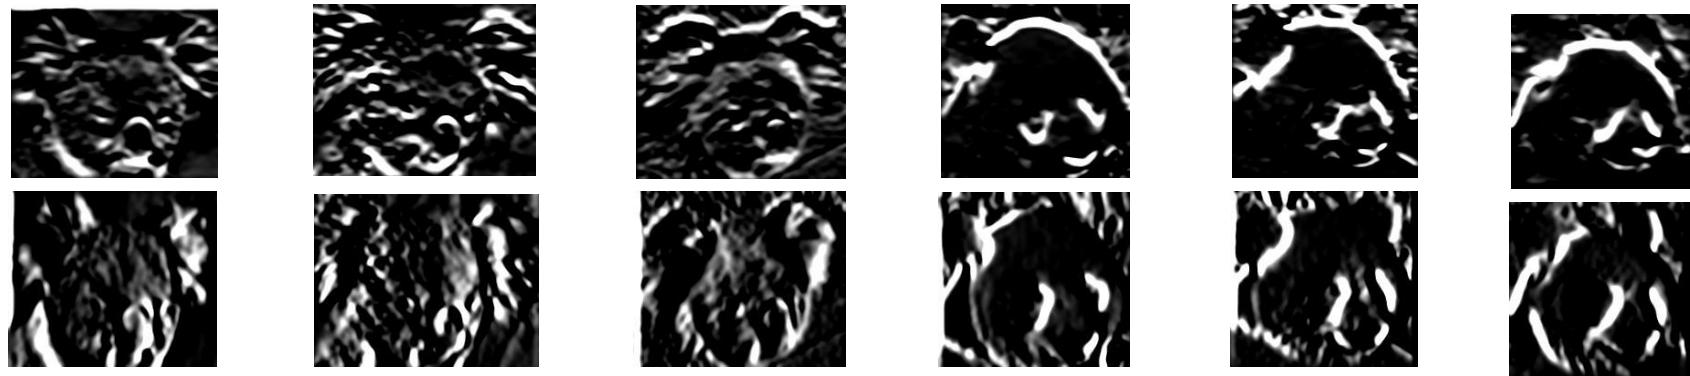

- Color or grayscale-based appearance description can be sensitive to illumination and intra-class appearance variation

Cartoon example:
an albino koala

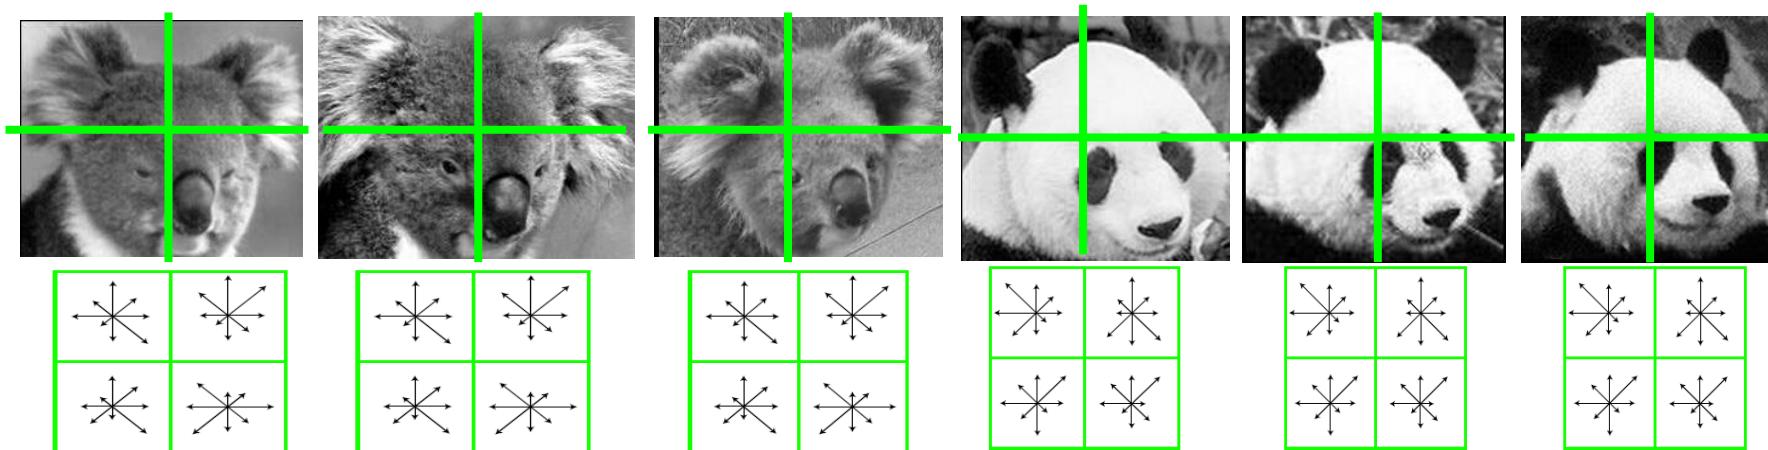

Gradient-based representations

- Consider edges, contours, and (oriented) intensity gradients

Gradient-based representations

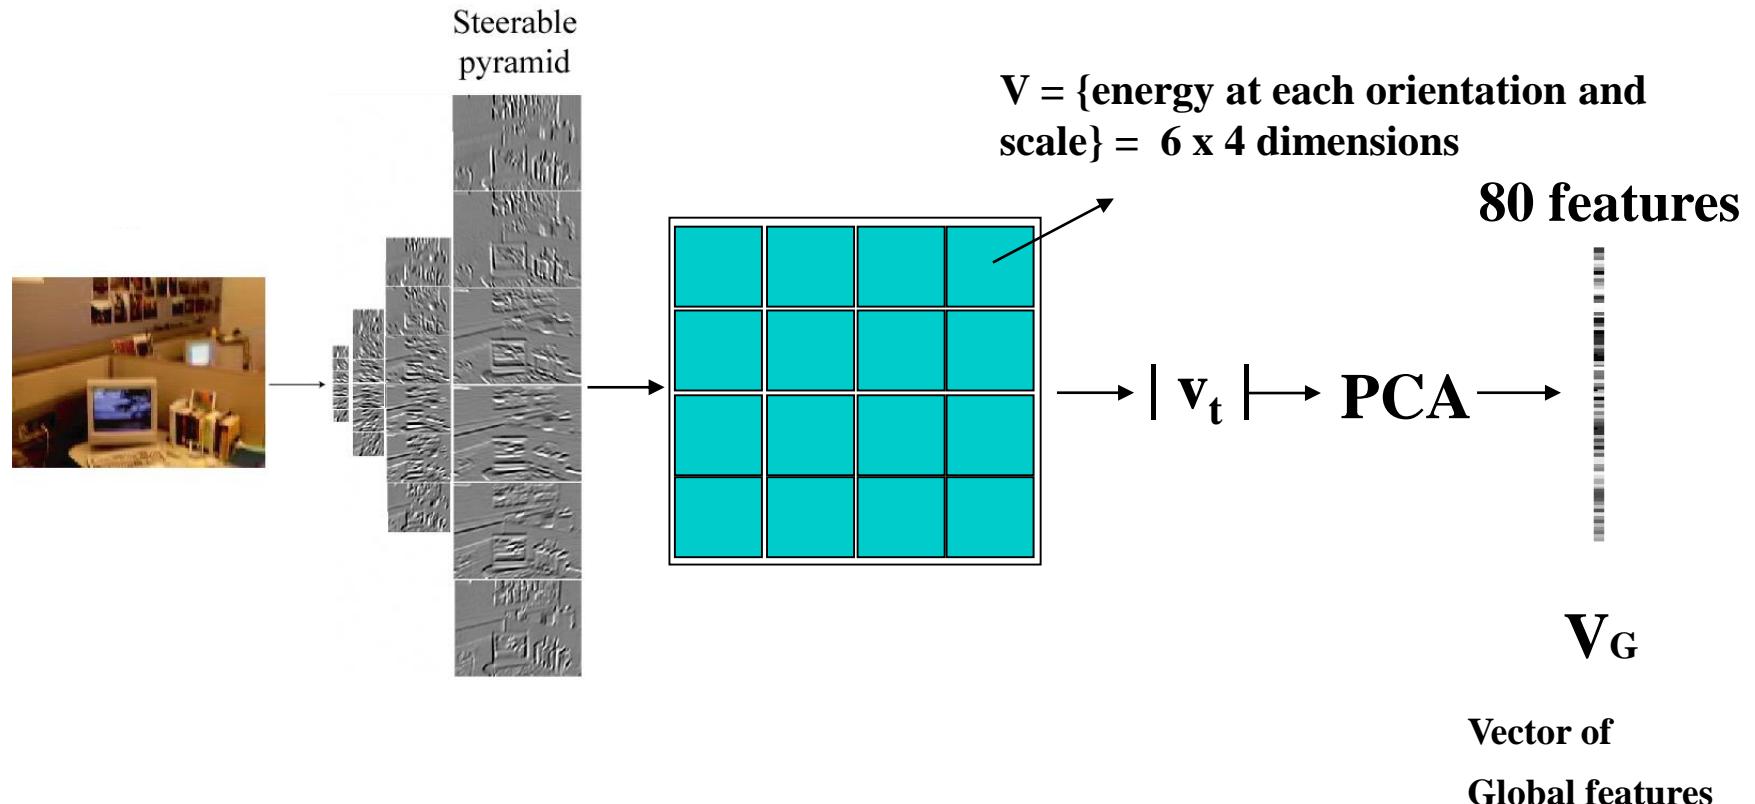

- Consider edges, contours, and (oriented) intensity gradients

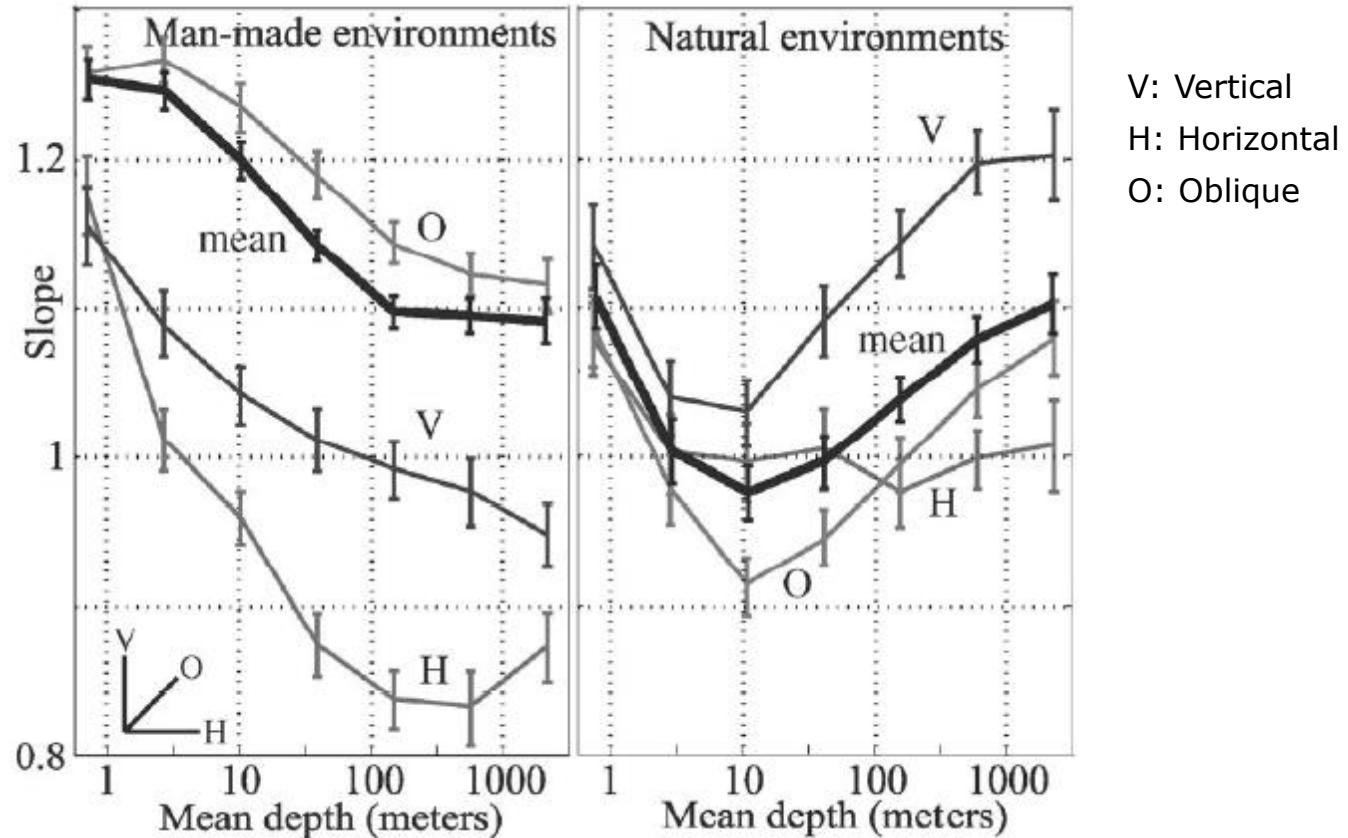

- Summarize local distribution of gradients with histogram
 - Locally orderless: offers invariance to small shifts and rotations
 - Contrast-normalization: try to correct for variable illumination

GIST

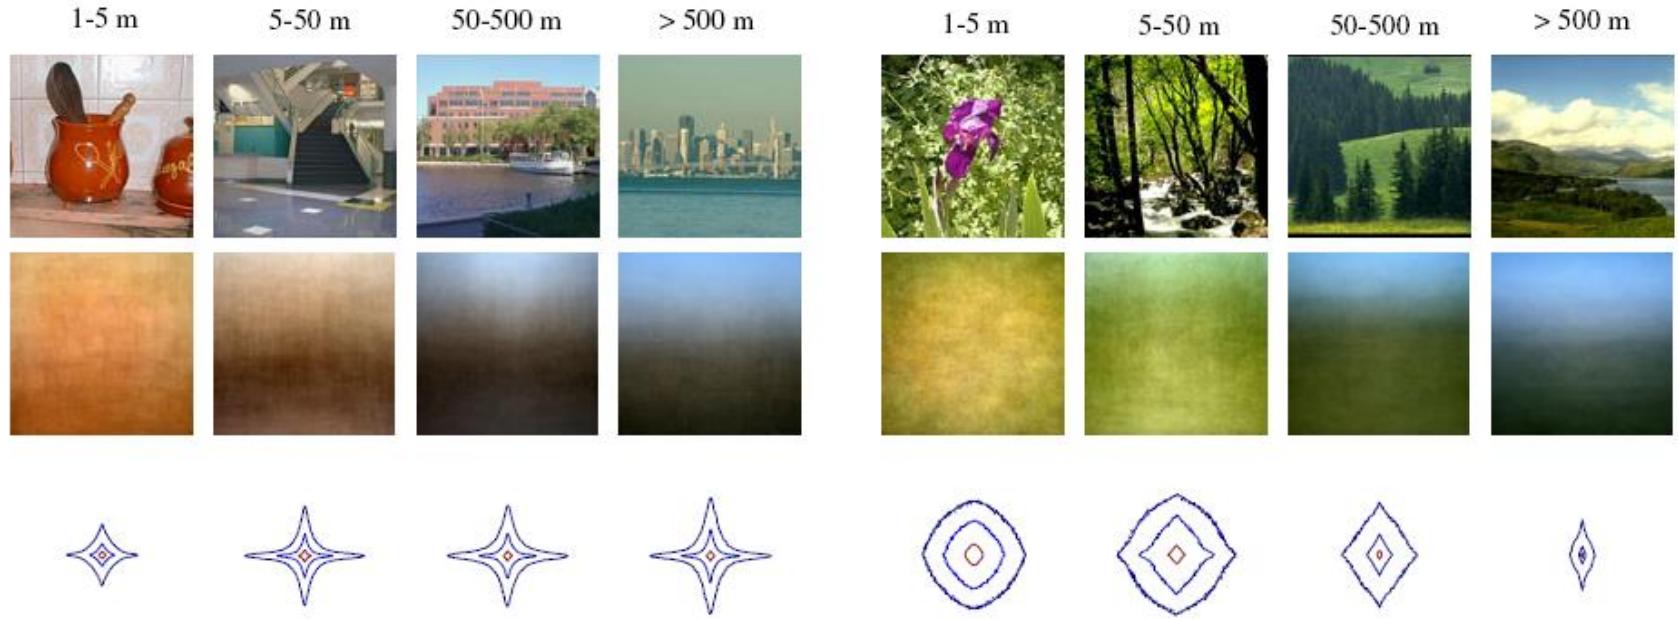

Representing Image Structure with “GIST”

What do Images Statistics say about Depth?

Scene Scale

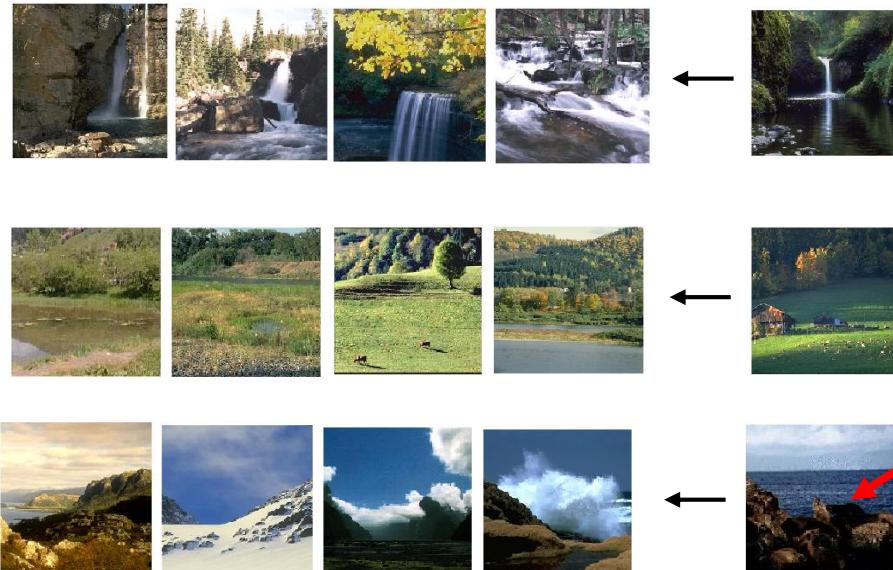

- ❑ “The point of view that any given observer adopts on a specific scene is constrained by the volume of the scene.”
- ❑ How does the amount of clutter vary against scene scale in man-made environments? In natural environments?

Categorization of Natural Scenes

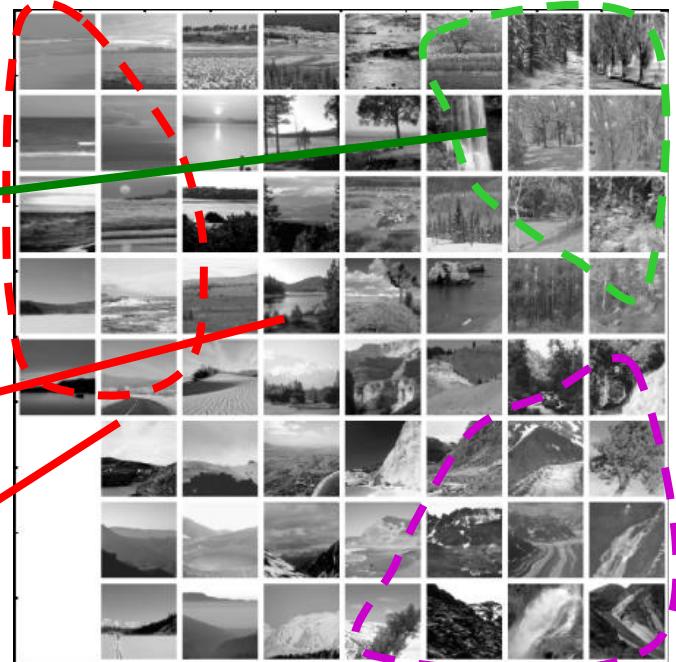

Confusion Matrix (in % using Layout template) :

Classification of prototypical scenes (400 / category)

| | Coast | Countryside | Forest | Mountain |
|-------------|-------|-------------|--------|----------|
| Coast | 88.6 | 8.9 | 1.2 | 1.3 |
| Countryside | 9.8 | 85.2 | 3.7 | 1.3 |
| Forest | 0.4 | 3.6 | 91.5 | 4.5 |
| Mountain | 0.4 | 4.6 | 3.8 | 91.2 |

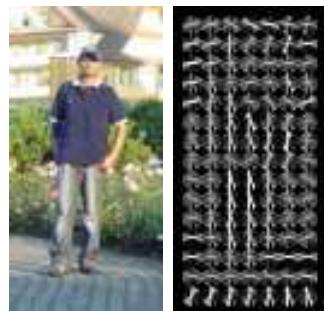

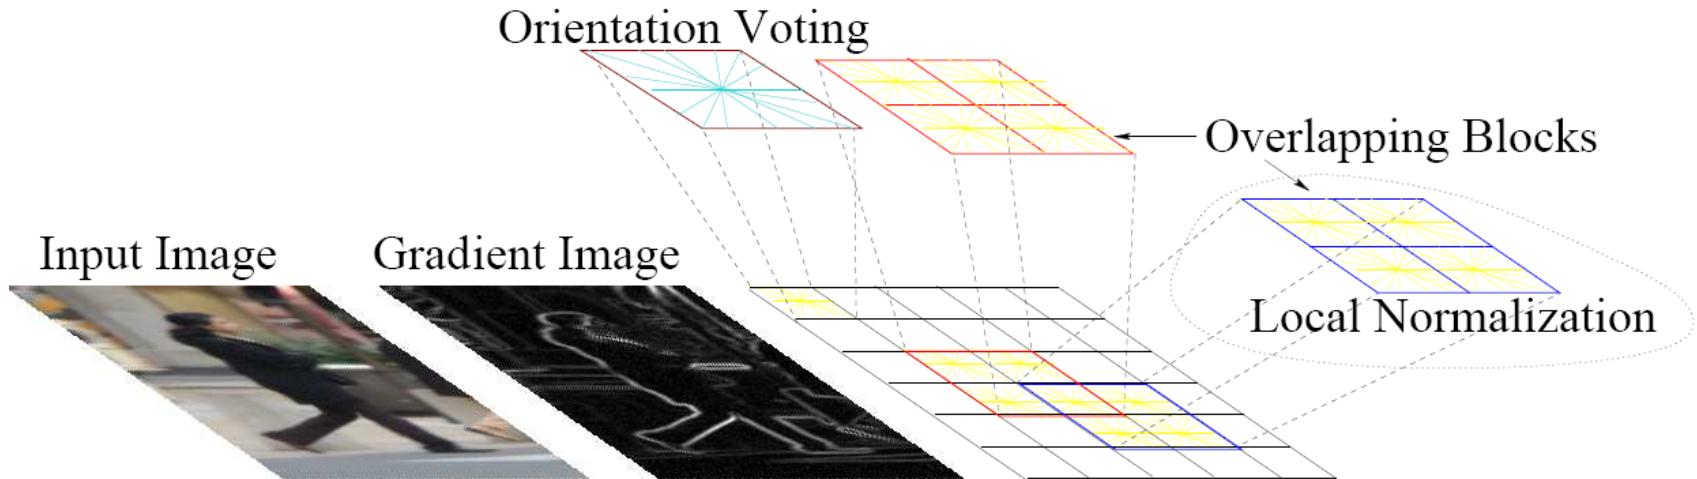

Local organization:
correct for 92 % images
(4 similar images on 7 K-NN)

HOG

Gradient-based representations: Histograms of oriented gradients (HoG)

Map each grid cell in the input window to a histogram counting the gradients per orientation.

Boosted Face Detection with Gradient Features

Gradient-based representations: Rectangular features

Compute differences between sums of pixels in rectangles

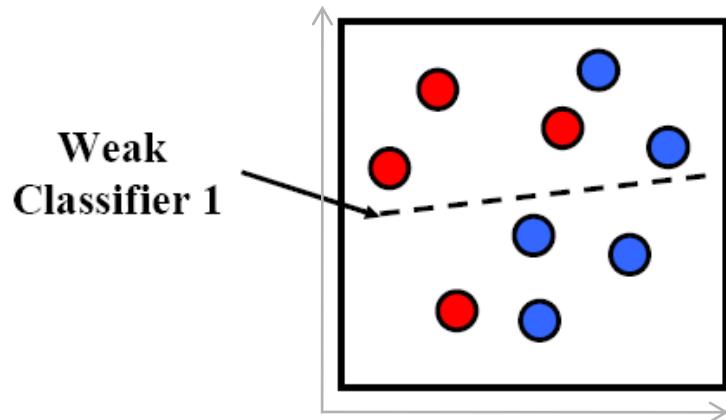

Captures contrast in adjacent spatial regions, efficient to compute

Each feature parameterized by scale, position, type.

Boosting

- Build a strong classifier by combining number of “weak classifiers”, which need only be better than chance
- Sequential learning process: at each iteration, add a weak classifier
- Flexible to choice of weak learner
 - including fast simple classifiers that alone may be inaccurate
- We'll look at Freund & Schapire's AdaBoost algorithm
 - Easy to implement
 - Base learning algorithm for Viola-Jones face detector

AdaBoost: Intuition

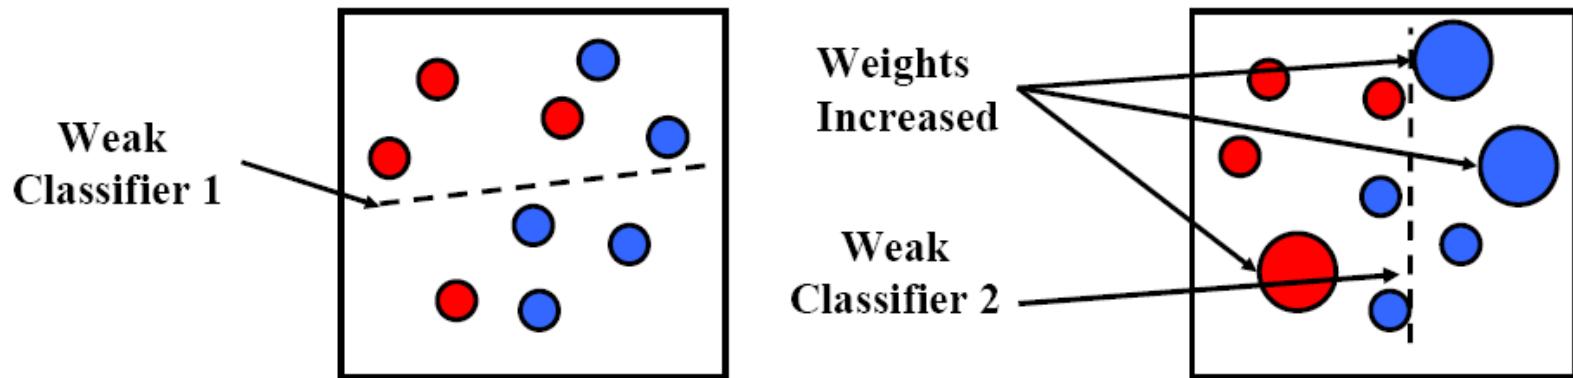

Consider a 2-d feature space with **positive** and **negative** examples.

Each weak classifier splits the training examples with at least 50% accuracy.

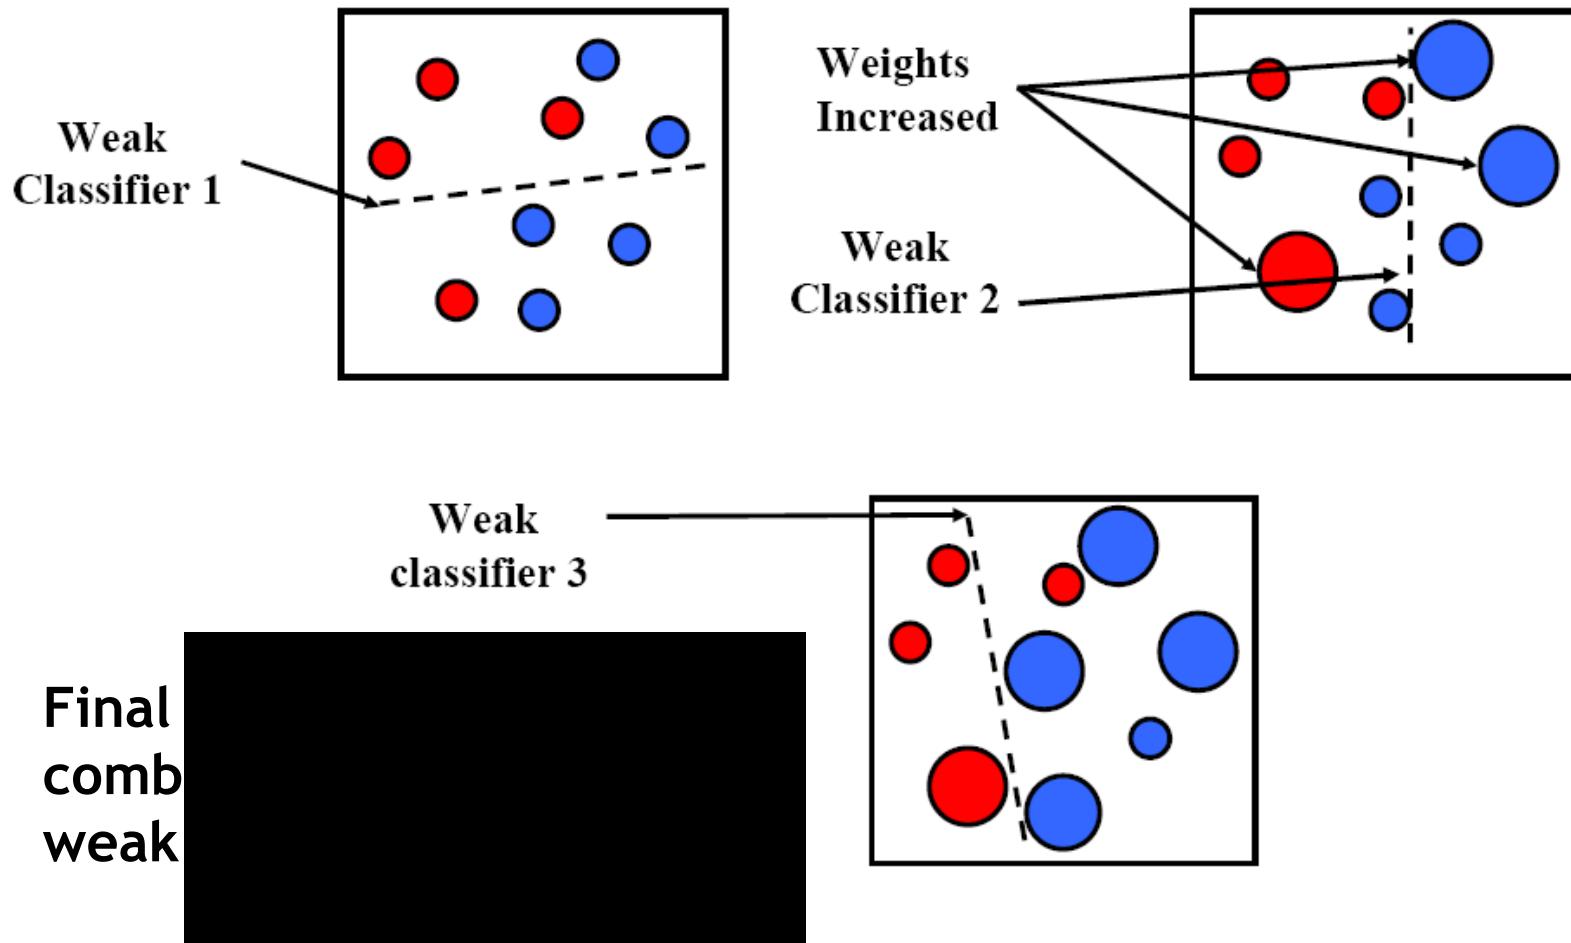

Examples misclassified by a previous weak learner are given more emphasis at future rounds.

Figure adapted from Freund and Schapire

AdaBoost: Intuition

AdaBoost: Intuition

- Given example images $(x_1, y_1), \dots, (x_n, y_n)$ where $y_i = 0, 1$ for negative and positive examples respectively.
- Initialize weights $w_{1,i} = \frac{1}{2m}, \frac{1}{2l}$ for $y_i = 0, 1$ respectively, where m and l are the number of negatives and positives respectively.
- For $t = 1, \dots, T$:

- Normalize the weights,

$$w_{t,i} \leftarrow \frac{w_{t,i}}{\sum_{j=1}^n w_{t,j}}$$

so that w_t is a probability distribution.

- For each feature, j , train a classifier h_j which is restricted to using a single feature. The error is evaluated with respect to w_t , $\epsilon_j = \sum_i w_i |h_j(x_i) - y_i|$.
- Choose the classifier, h_t , with the lowest error ϵ_t .
- Update the weights:

$$w_{t+1,i} = w_{t,i} \beta_t^{1-\epsilon_i}$$

where $e_i = 0$ if example x_i is classified correctly, $e_i = 1$ otherwise, and $\beta_t = \frac{\epsilon_t}{1-\epsilon_t}$.

- The final strong classifier is:

$$h(x) = \begin{cases} 1 & \sum_{t=1}^T \alpha_t h_t(x) \geq \frac{1}{2} \sum_{t=1}^T \alpha_t \\ 0 & \text{otherwise} \end{cases}$$

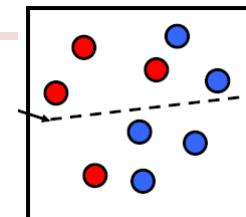

where $\alpha_t = \log \frac{1}{\beta_t}$

AdaBoost Algorithm

Start with

uniform
weights on
training
examples

For T rounds

$\{x_1, \dots, x_n\}$

Evaluate

weighted error
for each
feature, pick
best.

Re-weight the examples:

Incorrectly classified \rightarrow more weight

Correctly classified \rightarrow less weight

Final classifier is combination of
the weak ones, weighted
according to error they had.

Freund & Schapire 1990

Example: Face detection

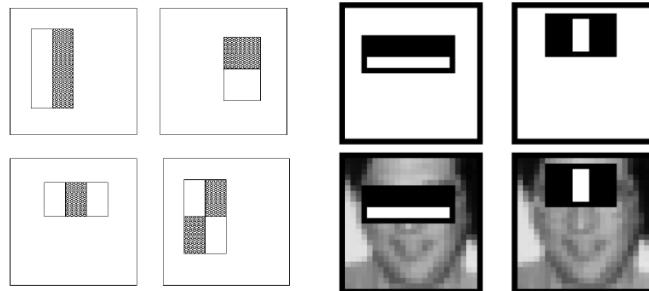

- Frontal faces are a good example of a class where global appearance models + a sliding window detection approach fit well:
 - Regular 2D structure
 - Center of face almost shaped like a “patch”/window

- Now we'll take AdaBoost and see how the Viola-Jones face detector works

Feature extraction

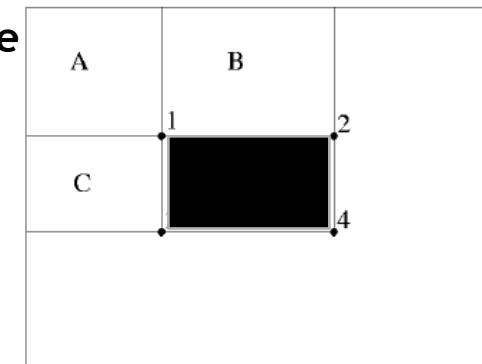

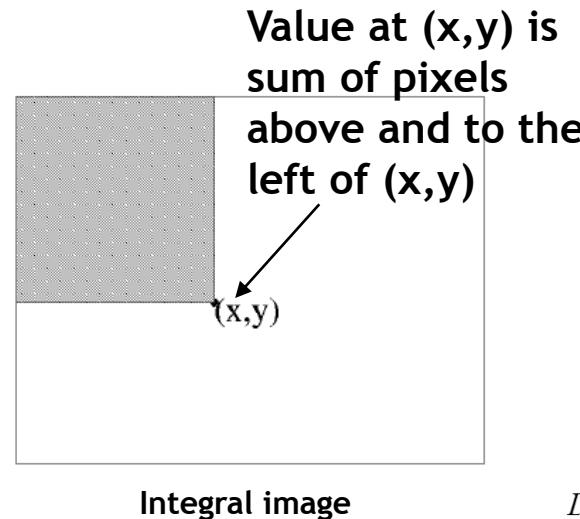

“Rectangular” filters

Feature output is difference between adjacent regions

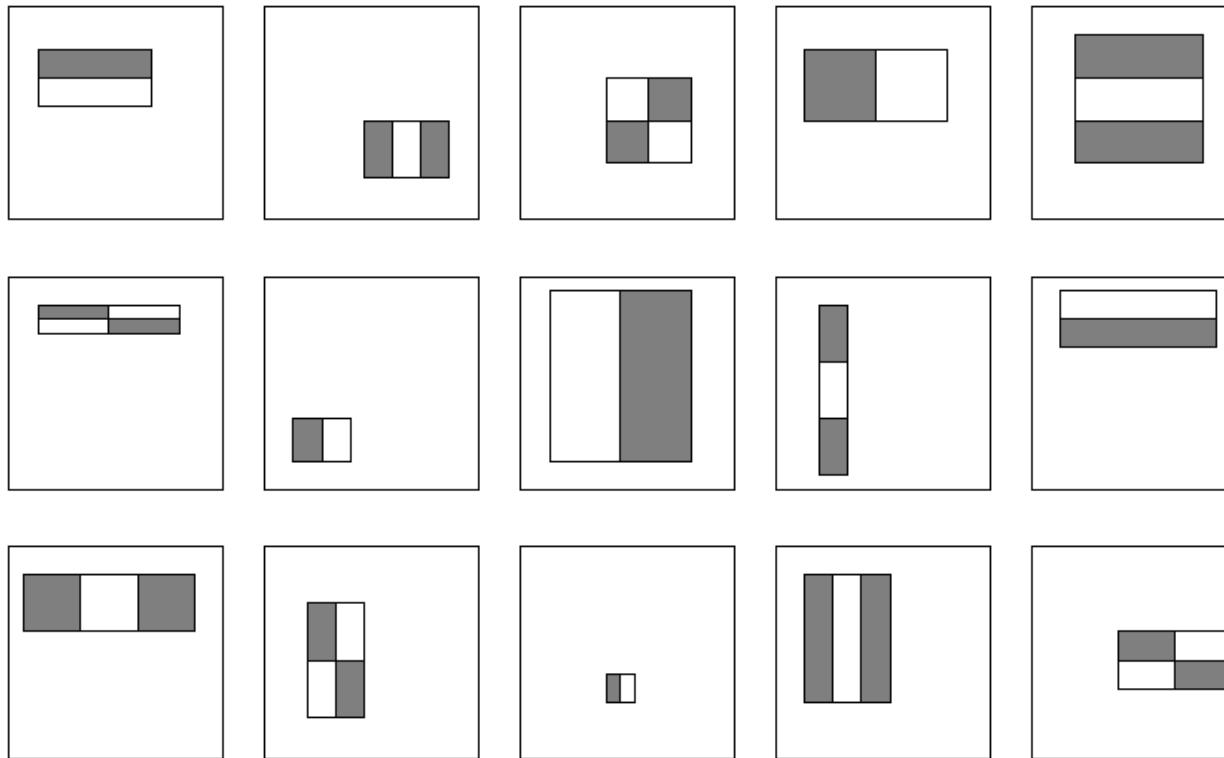

Efficiently computable with integral image: any sum can be computed in constant time

Avoid scaling images → scale features directly for same cost

$$\begin{aligned}D &= 1 + 4 - (2 + 3) \\&= A + (A + B + C + D) - (A + C + A + B) \\&= D\end{aligned}$$

Large library of filters

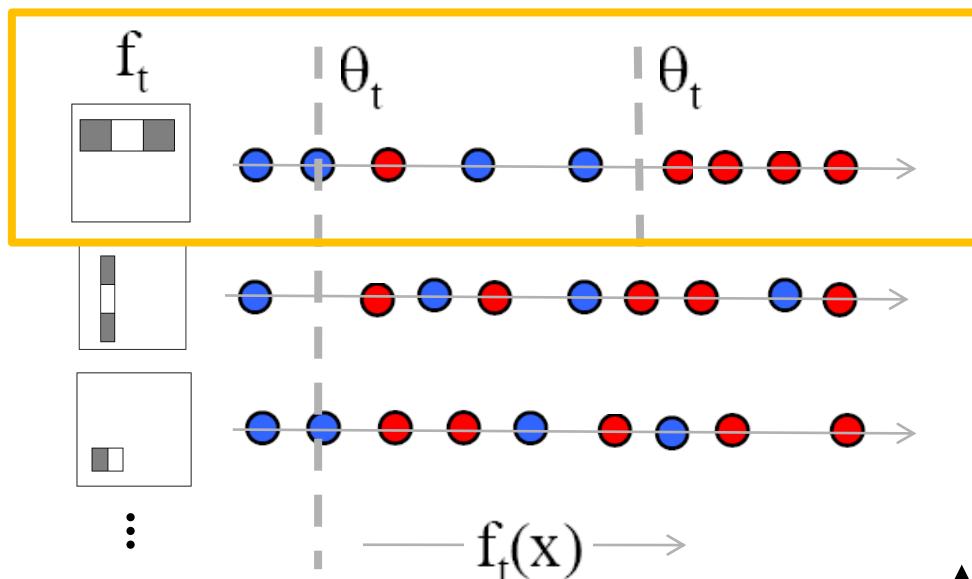

**Considering all possible filter parameters:
position, scale,
and type:
180,000+
possible features
associated with
each 24×24
window**

Use AdaBoost both to select the informative features and to form the classifier

AdaBoost for feature+classifier selection

- Want to select the single rectangle feature and threshold that best separates **positive** (faces) and (non-faces) training examples, in terms of *weighted* error.

Outputs of a possible rectangle feature on faces and non-faces.

Resulting weak classifier:

$$h_t(x) = \begin{cases} +1 & \text{if } f_t(x) > \theta_t \\ -1 & \text{otherwise} \end{cases}$$

For next round, reweight the examples according to errors, choose another filter/threshold combo.

- Given example images $(x_1, y_1), \dots, (x_n, y_n)$ where $y_i = 0, 1$ for negative and positive examples respectively.
- Initialize weights $w_{1,i} = \frac{1}{2m}, \frac{1}{2l}$ for $y_i = 0, 1$ respectively, where m and l are the number of negatives and positives respectively.
- For $t = 1, \dots, T$:

- Normalize the weights,

$$w_{t,i} \leftarrow \frac{w_{t,i}}{\sum_{j=1}^n w_{t,j}}$$

so that w_t is a probability distribution.

- For each feature, j , train a classifier h_j which is restricted to using a single feature. The error is evaluated with respect to w_t , $\epsilon_j = \sum_i w_i |h_j(x_i) - y_i|$.
- Choose the classifier, h_t , with the lowest error ϵ_t .
- Update the weights:

$$w_{t+1,i} = w_{t,i} \beta_t^{1-\epsilon_i}$$

where $\epsilon_i = 0$ if example x_i is classified correctly, $\epsilon_i = 1$ otherwise, and $\beta_t = \frac{1}{\epsilon_t}$.

- The final strong classifier is:

$$h(x) = \begin{cases} 1 & \sum_{t=1}^T \alpha_t h_t(x) \geq \frac{1}{2} \sum_{t=1}^T \alpha_t \\ 0 & \text{otherwise} \end{cases}$$

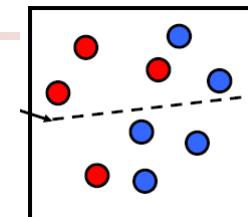

where $\alpha_t = \log \frac{1}{\beta_t}$

AdaBoost Algorithm

Start with

uniform
weights on
training
examples

For T rounds

$\{x_1, \dots, x_n\}$

Evaluate

weighted error
for each
feature, pick
best.

Re-weight the examples:

Incorrectly classified \rightarrow more
weight

Correctly classified \rightarrow less weight

Final classifier is combination of
the weak ones, weighted
according to error they had.

Freund & Schapire 1990

AdaBoost for Efficient Feature Selection

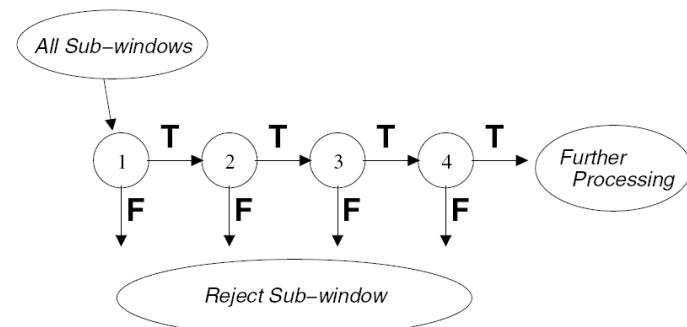

- Image Features = Weak Classifiers
- For each round of boosting:
 - Evaluate each rectangle filter on each example
 - Sort examples by filter values
 - Select best threshold for each filter (min error)
 - Sorted list can be quickly scanned for the optimal threshold
 - Select best filter/threshold combination
 - Weight on this feature is a simple function of error rate
 - Reweight examples

-
- Even if the filters are fast to compute, each new image has a lot of possible windows to search.
 - How to make the detection more efficient?

Cascading classifiers for detection

For efficiency, apply less accurate but faster classifiers first to immediately discard windows that clearly appear to be negative; e.g.,

- Filter for promising regions with an initial inexpensive classifier
- Build a chain of classifiers, choosing cheap ones with low false negative rates early in the chain

Example application: faces in photos

 All Web People Objects Tags My Photos SEARCH Advanced

Riya Personal Search

Use our face recognition and text recognition, to search your personal photos

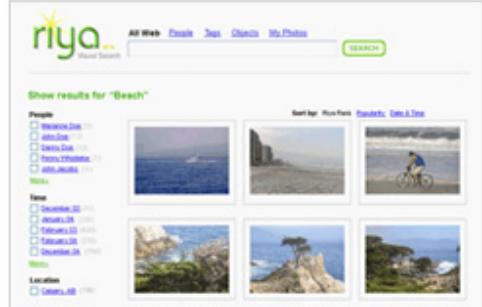

Upload your personal photos (public or privately)

Use our face and text recognition to auto tag your photos

Search & share photos with your friends

Riya's Personal Search lets you upload and search your own photos by name. You can keep them private or make them public and share with all Riya searchers. We allow you to use face and text recognition to search your own photos.

Highlights

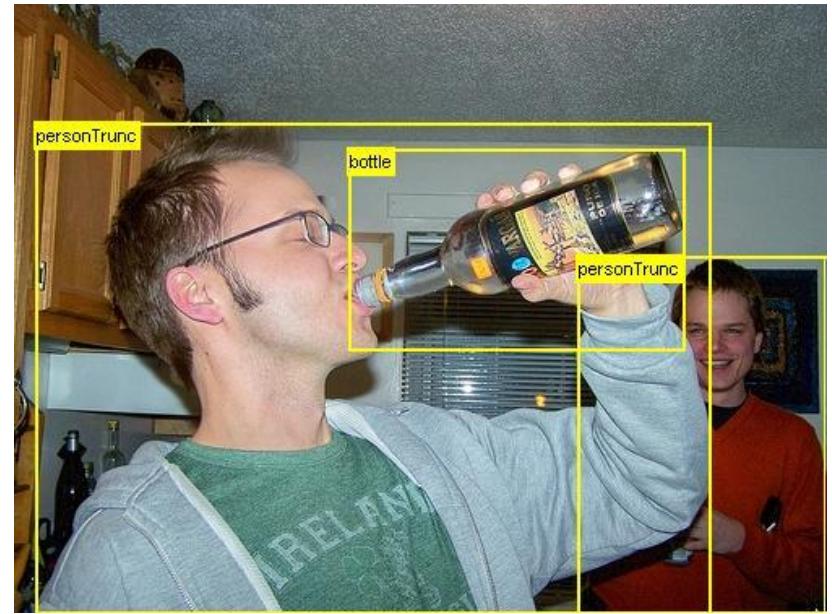

- Sliding window detection and global appearance descriptors:
 - Simple detection protocol to implement
 - Good feature choices critical
 - Past successes for certain classes

Limitations

- High computational complexity
 - For example: 250,000 locations x 30 orientations x 4 scales = 30,000,000 evaluations!
 - If training binary detectors independently, means cost increases linearly with number of classes
- With so many windows, false positive rate better be low

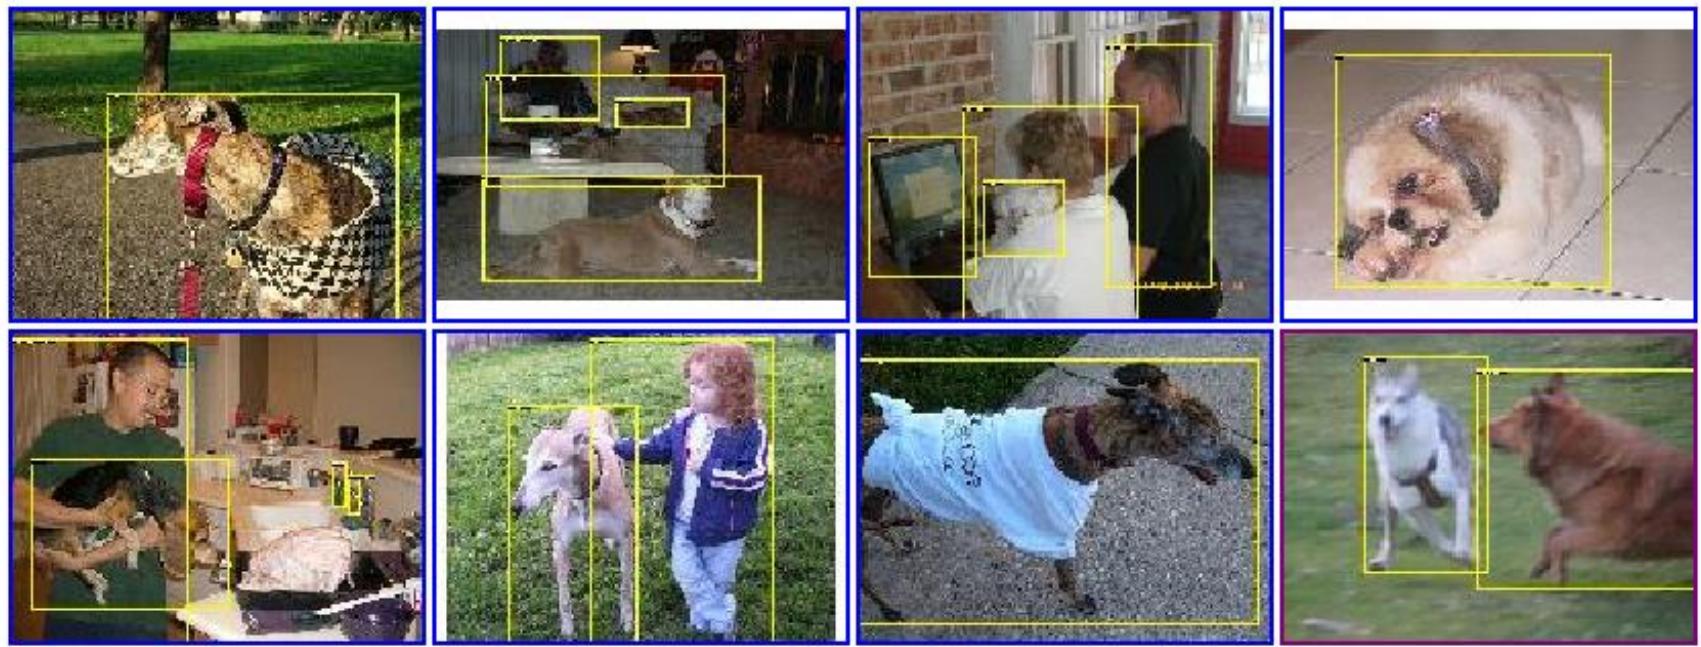

Limitations (continued)

- Not all objects are “box” shaped

Limitations (continued)

- Non-rigid, deformable objects not captured well with representations assuming a fixed 2d structure; or must assume fixed viewpoint
- Objects with less-regular textures not captured well with holistic appearance-based descriptions

Limitations (continued)

- If considering windows in isolation, context is lost

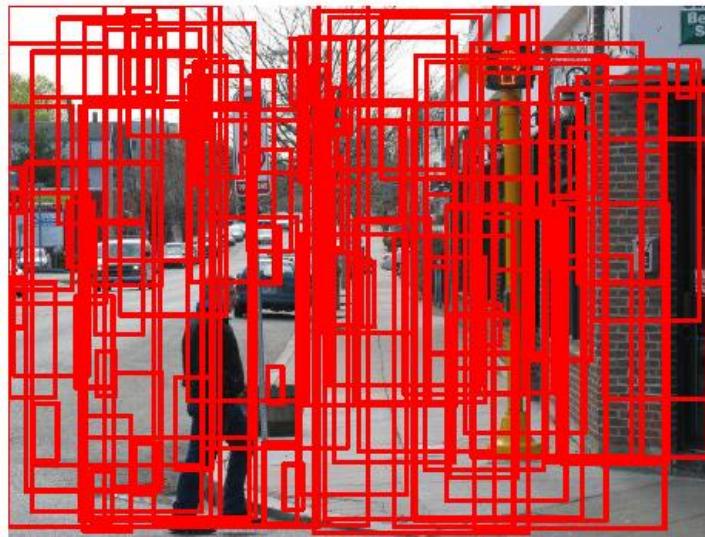

Sliding window

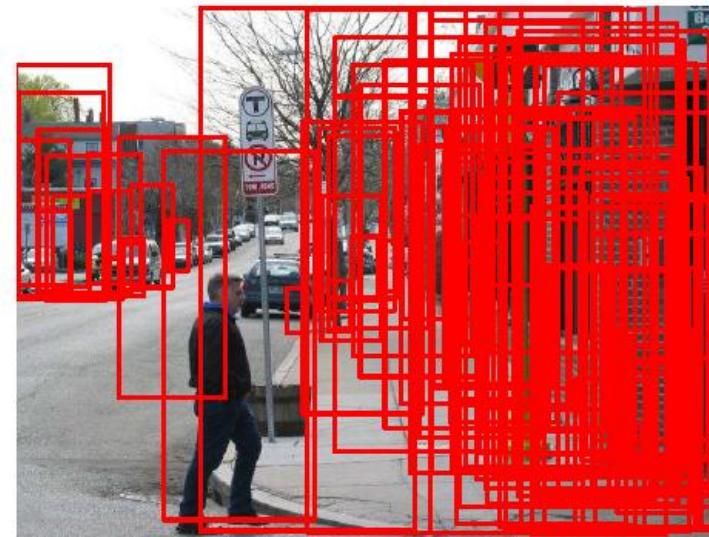

Detector's view

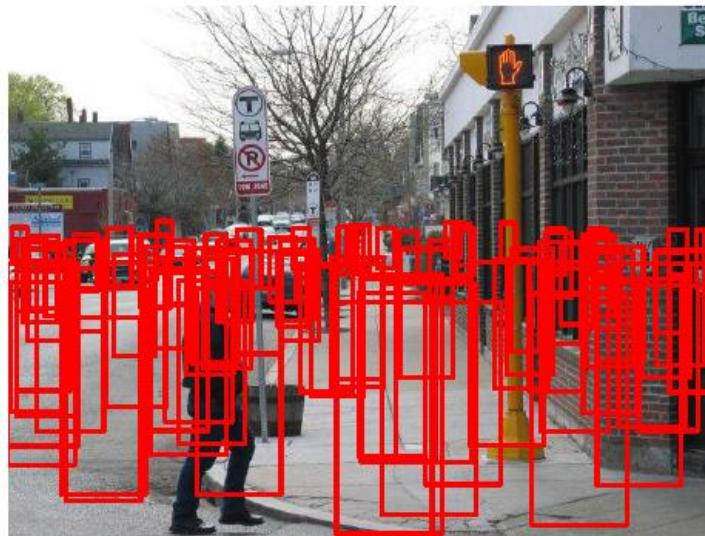

Context can constrain a sliding window search

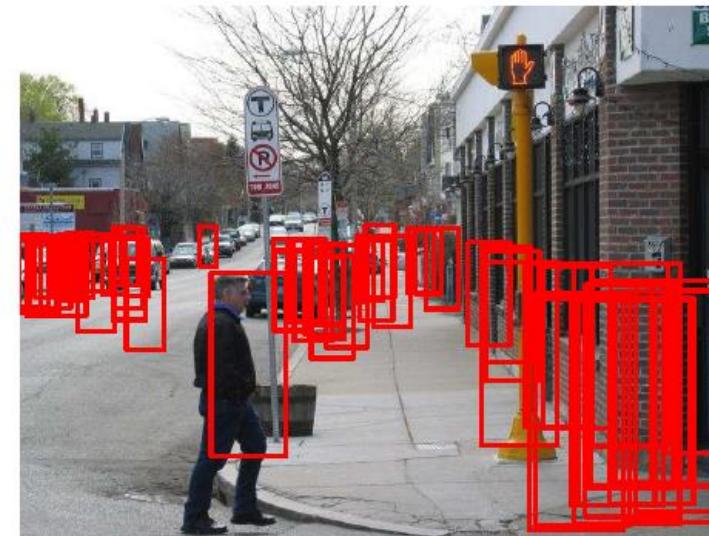

(b) $P(\text{person}) = \text{uniform}$

(d) $P(\text{person} \mid \text{geometry})$

(f) $P(\text{person} \mid \text{viewpoint})$

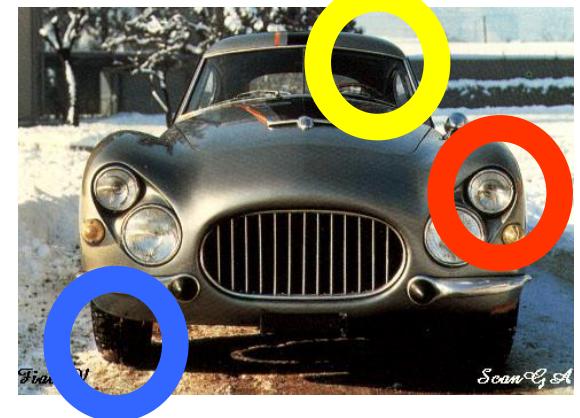

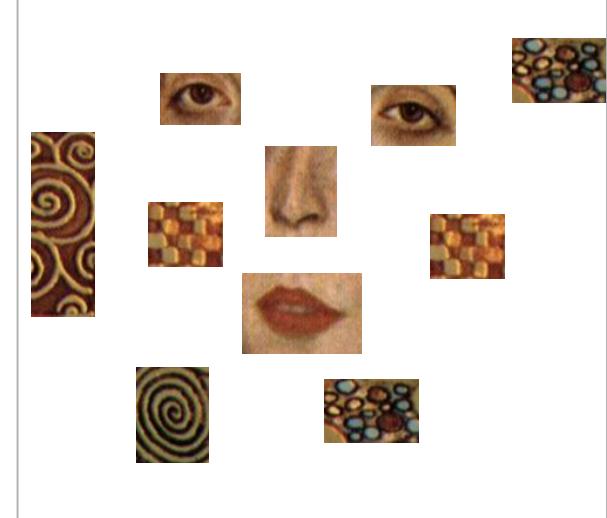

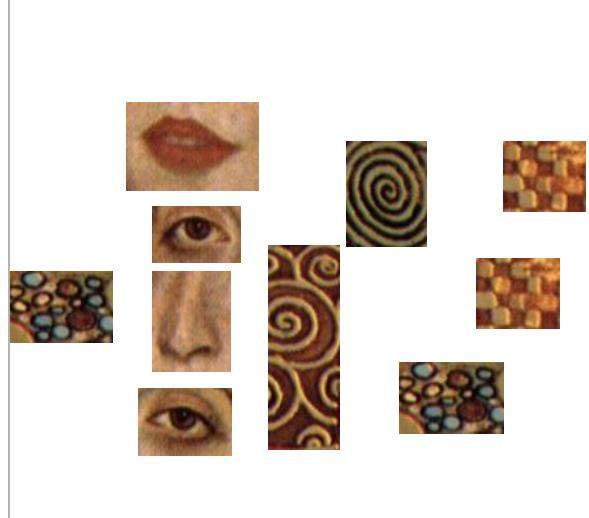

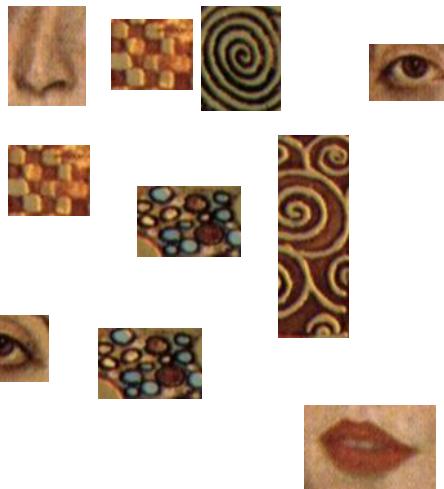

(g) $P(\text{person} \mid \text{viewpoint,geometry})$

Limitations (continued)

- In practice, often entails large, cropped training set (expensive)
- Requiring good match to a global appearance description can lead to sensitivity to partial occlusions

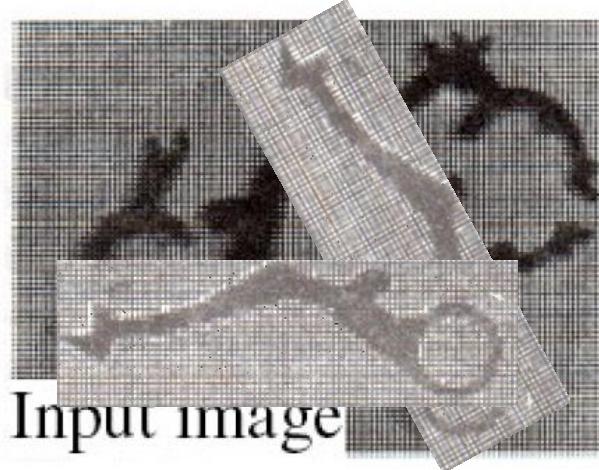

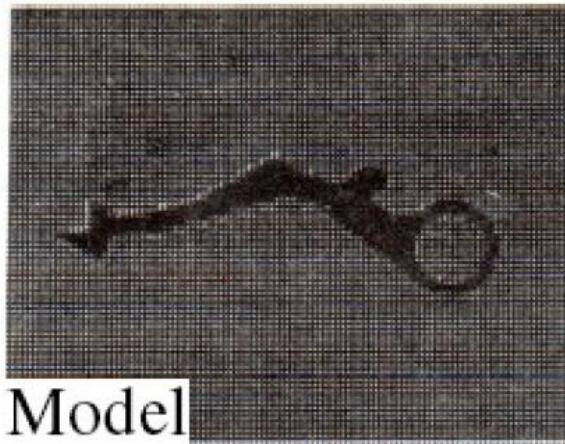

Models based on local features will
alleviate some of these limitations...

Local-feature Alignment

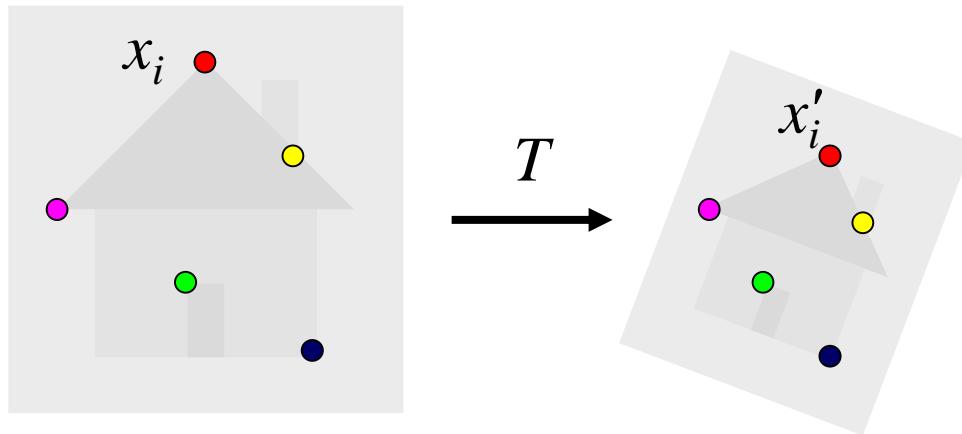

Hypothesize and test: main idea

- Given model of object
- New image: hypothesize object identity and pose
- Render object in camera
- Compare rendering to actual image: if close, good hypothesis.

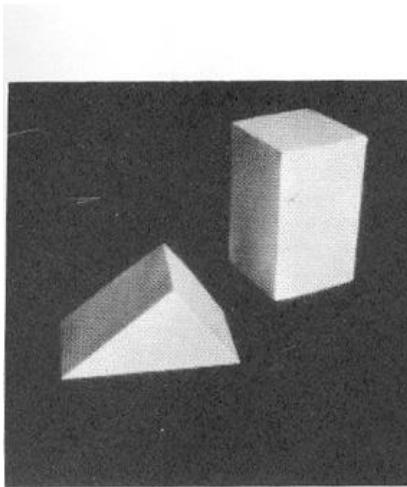

Recall: Alignment

- Alignment: fitting a model to a transformation between pairs of features (*matches*) in two images

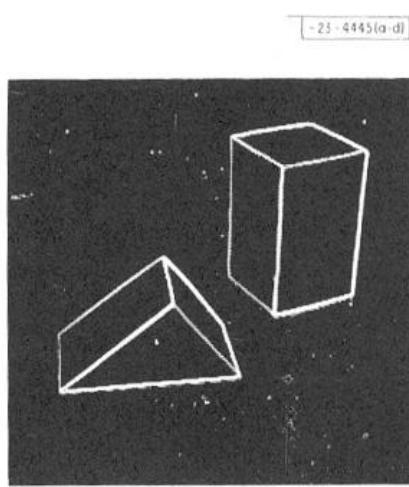

Find transformation T
that minimizes
$$\sum_i \text{residual}(T(x_i), x'_i)$$

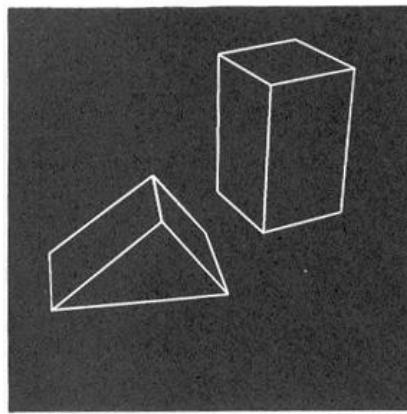

Alignment-based

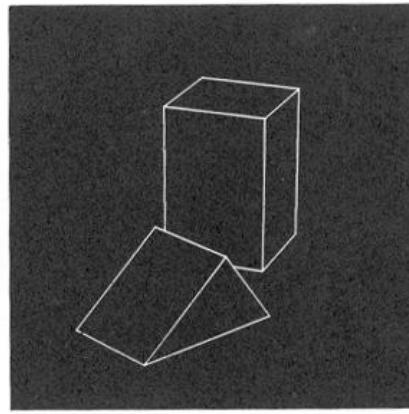

(a) Original picture.

(b) Differentiated picture.

(c) Line drawing.

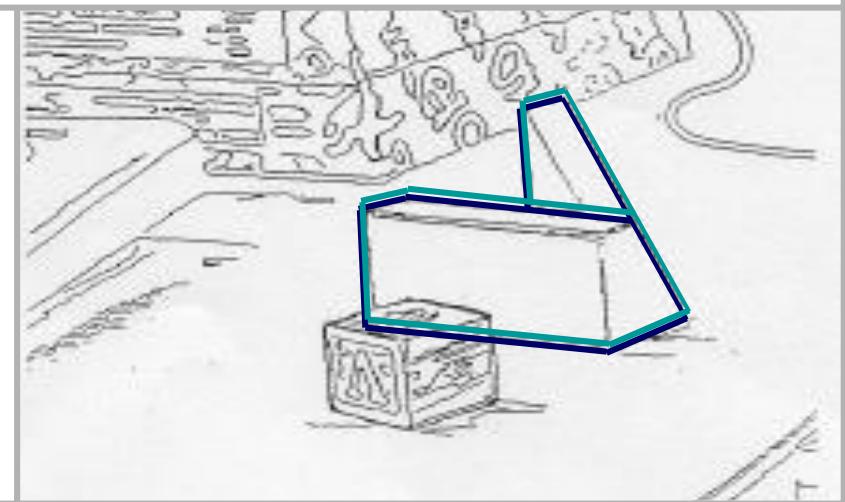

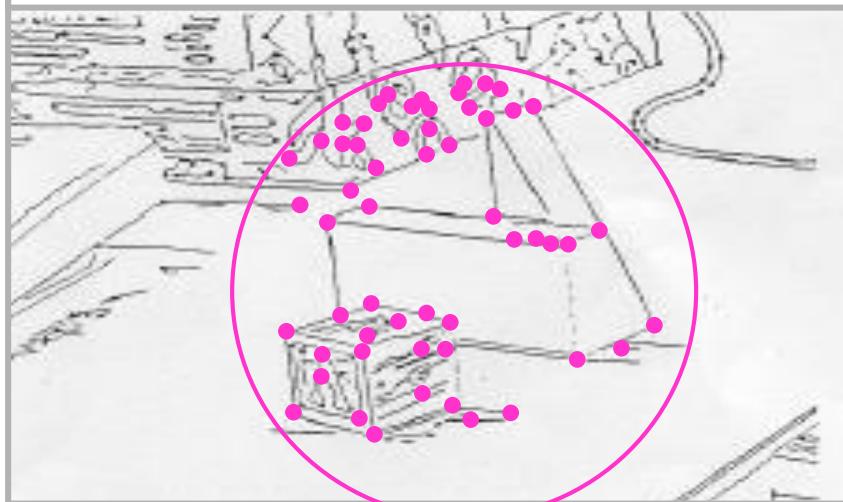

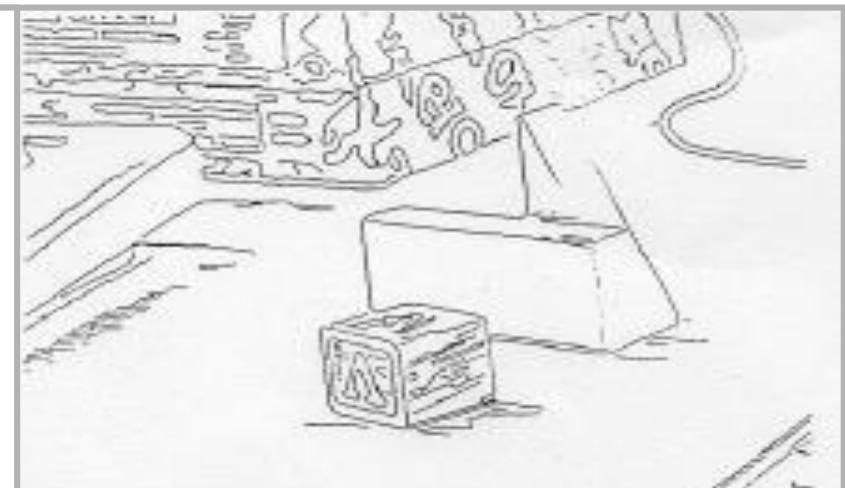

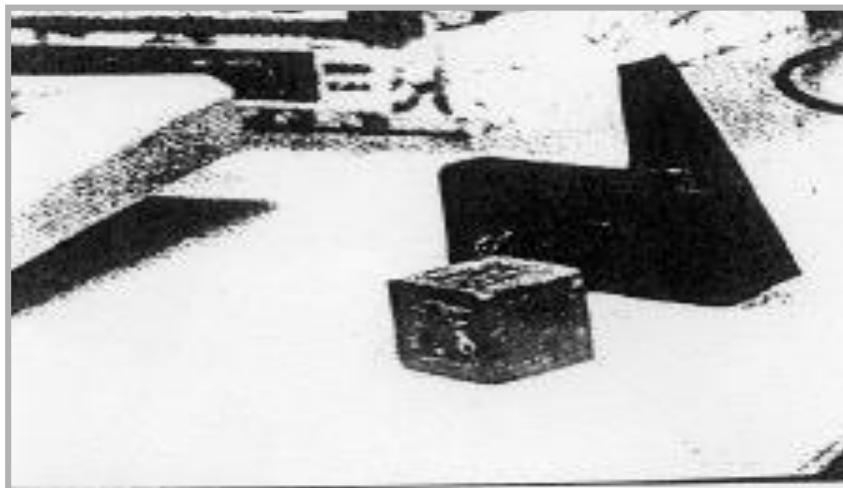

(d) Rotated view.

Alignment-based

ACRONYM (Brooks
and Binford, 1981)

How to form a hypothesis?

Given a particular model object, we can estimate the *correspondences* between image and model features

Use correspondence to estimate model pose relative to object coordinate frame

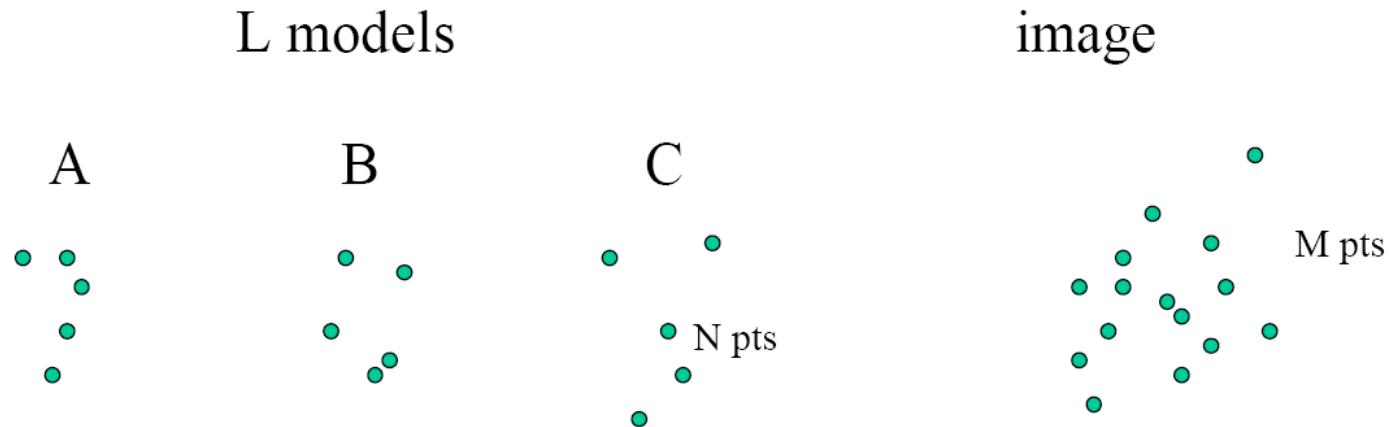

Generating hypotheses

We want a good correspondence between model features and image features.

- Brute force?

Brute force hypothesis generation

- For every possible model, try every possible subset of image points as matches for that model's points.
- Say we have L objects with N features, M features in image

Generating hypotheses

We want a good correspondence between model features and image features.

- Brute force?

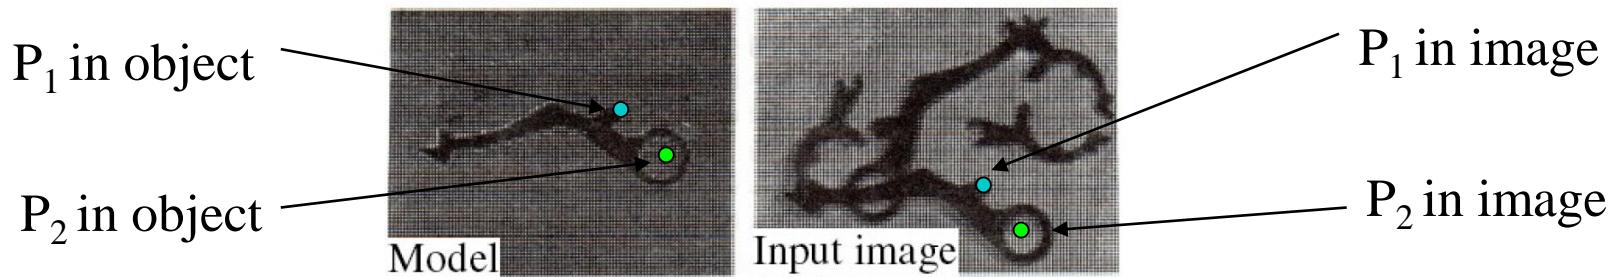

- **Pose consistency**, alignment: use subsets of features to estimate larger correspondence
- **Voting**, pose clustering

Pose consistency / alignment

- Key idea:
 - If we find good correspondences for a small set of features, it is easy to obtain correspondences for a much larger set.
- Strategy:
 - Generate hypotheses using small numbers of correspondences
 - Backproject: transform *all* model features to image features
 - Verify

Example: 2d affine mappings

- Say camera is looking down perpendicularly on planar surface

- We have two coordinate systems (object and image), and they are related by some affine mapping (rotation, scale, translation, shear).

Alignment: verification

- Given the back-projected model in the image:
 - Check if image edges coincide with predicted model edges
 - May be more robust if also require edges to have the same orientation
 - Consider texture in corresponding regions
- Possible issues?

Alignment: verification

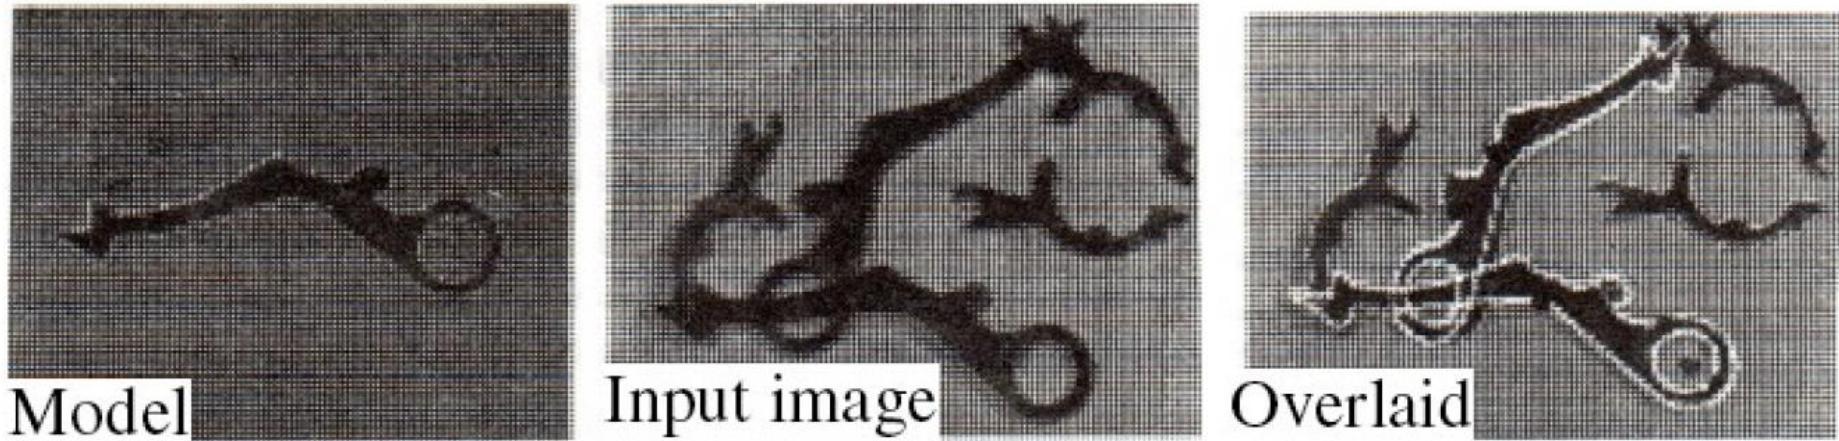

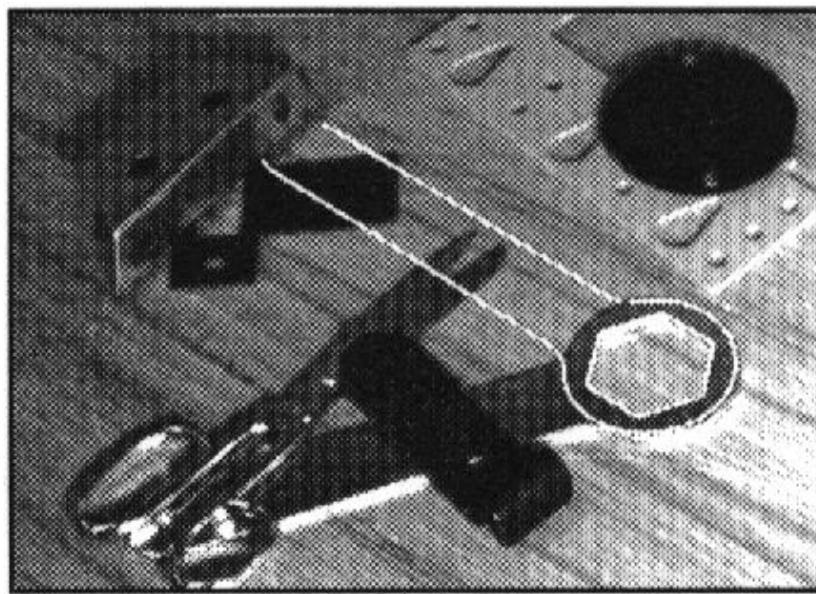

Figure from “Object recognition using alignment,” D.P. Huttenlocher and S. Ullman, Proc. Int. Conf. Computer Vision, 1986, copyright IEEE, 1986

Alignment: verification

Issue with hypothesis & test approach

- May have false matches
 - We want *reliable* features to form the matches
 - ◆ **Local invariant features** useful to find matches, and to verify hypothesis
(SIFT, etc.)
- May be too many hypotheses to consider
 - We want to look at the *most likely* hypotheses first
 - ◆ **Pose clustering (voting):** Narrow down number of hypotheses to verify by letting features *vote* on model parameters.

Pose clustering (voting)

- Narrow down the number of hypotheses to verify: identify those model poses that a lot of features agree on.
 - Use each group's correspondence to estimate pose
 - Vote for that object pose in accumulator array (one array per object if we have multiple models)
- Local invariant features can give more reliable matches and means of verification

Pose clustering and verification with SIFT

[Lowe]

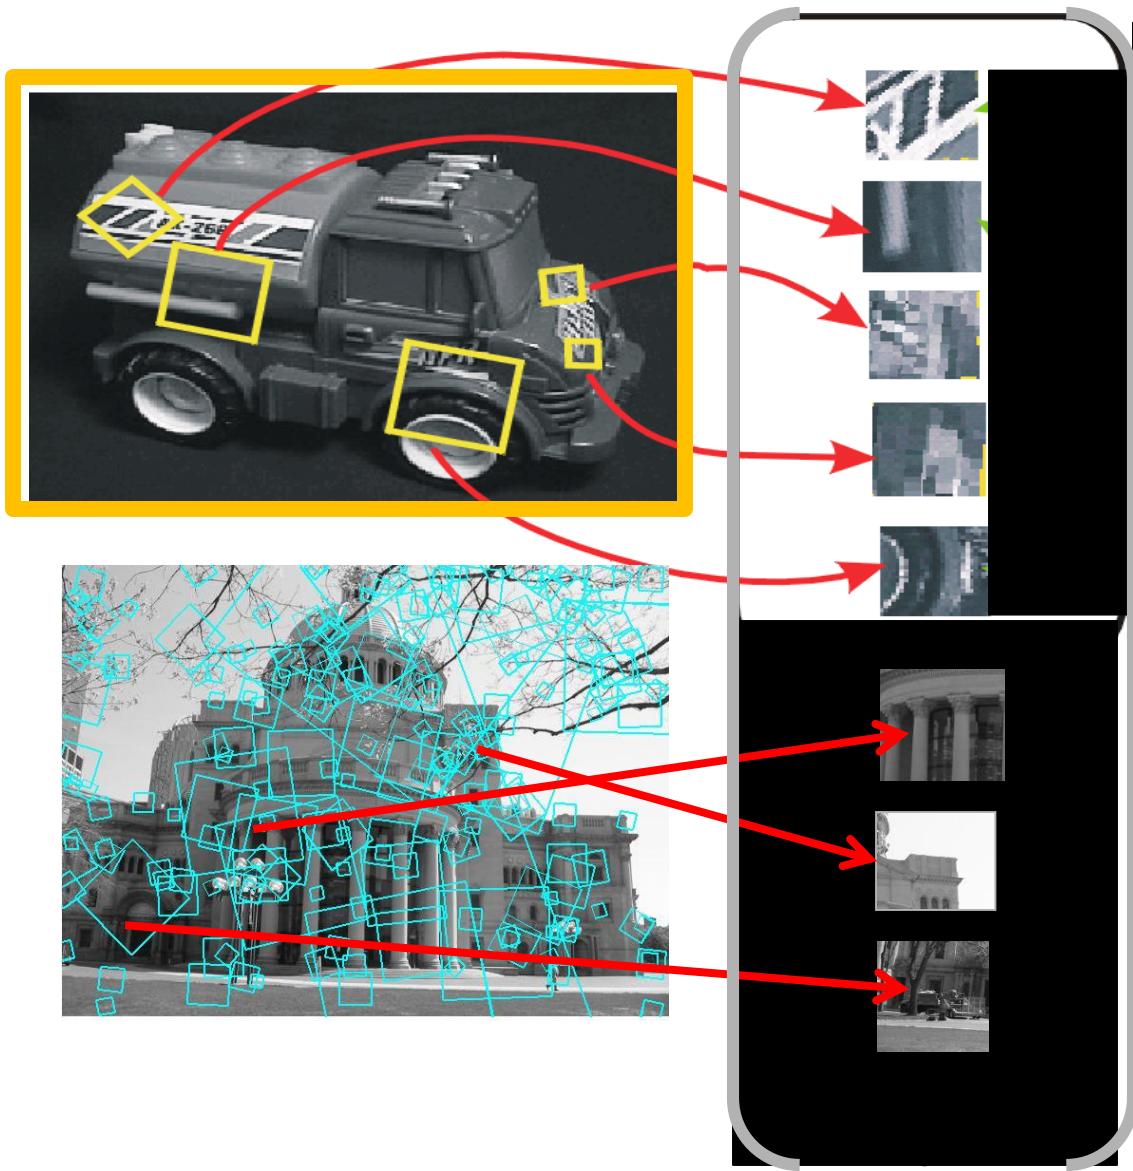

To detect **instances** of objects from a model base:

- 1) Index descriptors (distinctive features narrow possible matches)

Indexing local features

Pose clustering and verification with SIFT [Lowe]

To detect **instances** of objects from a model base:

- 1) Index descriptors (distinctive features narrow possible matches)
- 2) Generalized Hough transform to vote for poses (keypoints have record of parameters relative to model coordinate system)
- 3) Affine fit to check for agreement between model and image features (approximates perspective projection for planar objects)

Planar objects

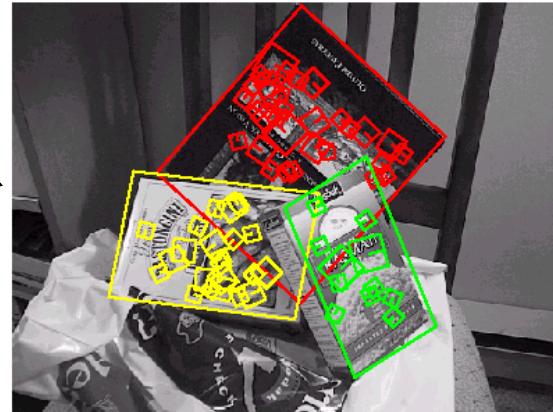

Model images and
their SIFT keypoints

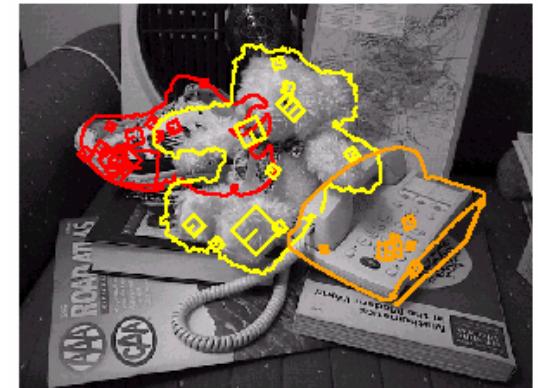

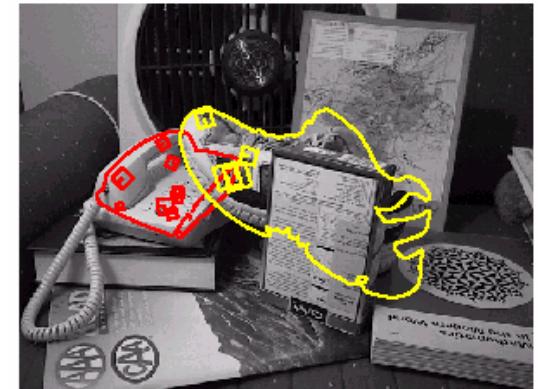

Input image

Model keypoints
that were used to
recognize, get
least squares
solution.

Recognition result

3d objects

Background subtract for
model boundaries

Objects recognized,
though affine model not
as accurate.

Recognition in spite
of occlusion

Recall: difficulties of voting

- Noise/clutter can lead to as many votes as true target
 - Bin size for the accumulator array must be chosen carefully
 - (Recall Hough Transform)
-
- In practice, good idea to make broad bins and spread votes to nearby bins, since verification stage can prune bad vote peaks.

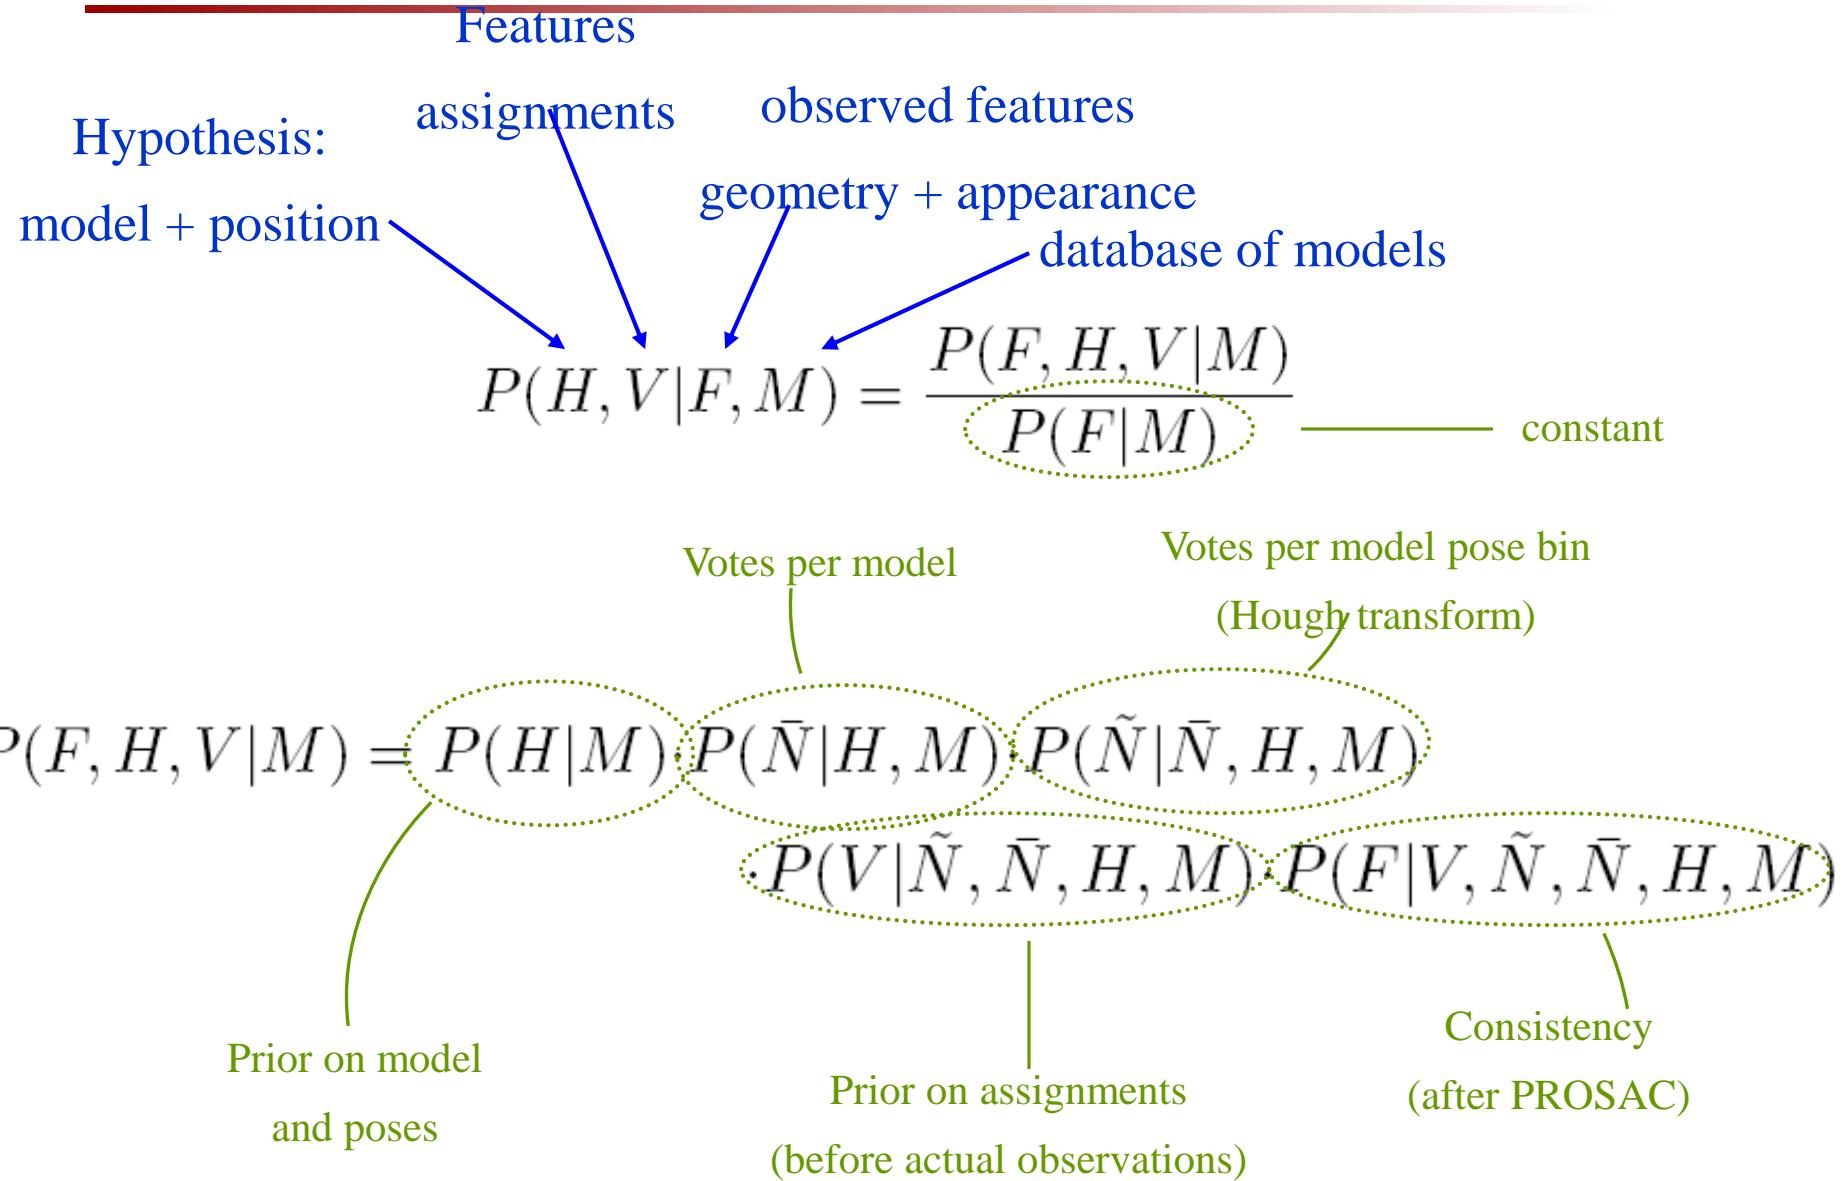

A probabilistic interpretation (and re-tuning) of Lowe's system:

P. Moreels and P. Perona, "**A probabilistic cascade of detectors for individual object recognition,**" European Conference on Computer Vision, 2008.

Coarse-to-Fine detection

- Progressively narrow down focus on correct region of hypothesis space
- Reject with little computation cost irrelevant regions of search space
- Use first information that is easy to obtain
- Simple building blocks organized in a cascade
- Probabilistic interpretation of each step

Score of an extended hypothesis

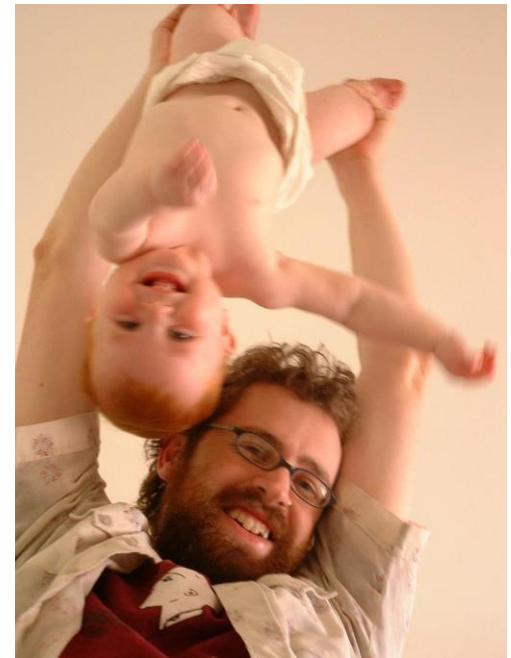

Coarse data : prior knowledge

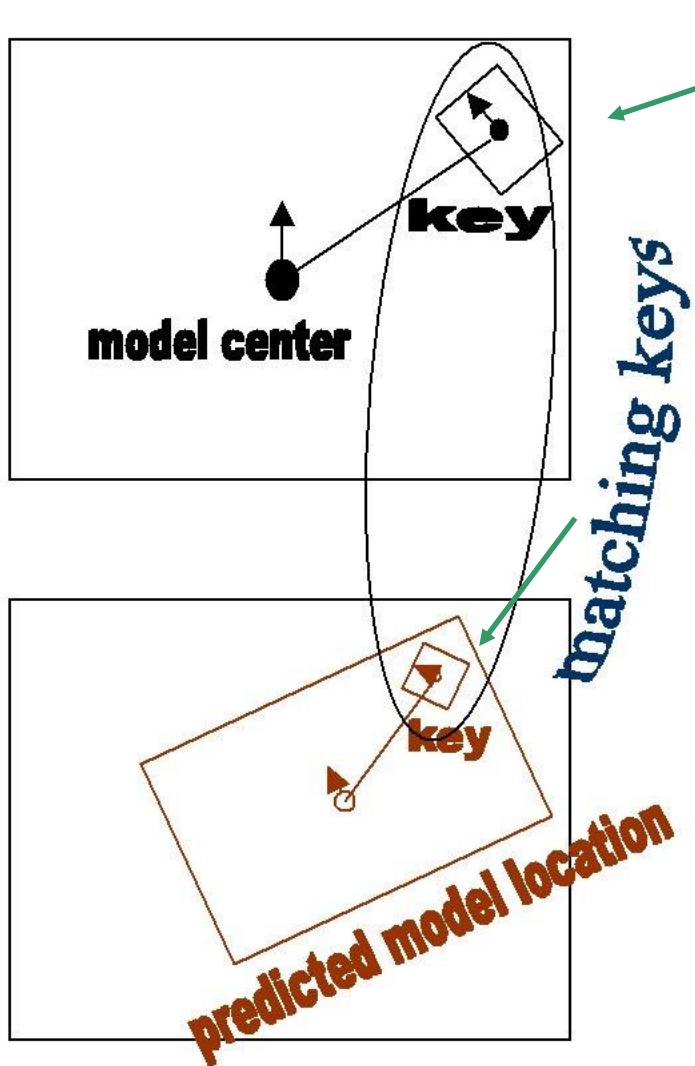

- Which objects are likely to be there, which pose are they likely to have ?

unlikely
situations

Coarse Hough transform

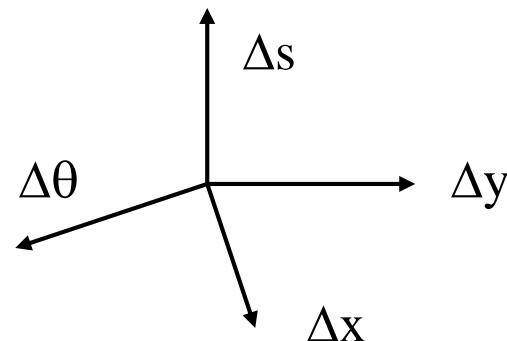

$(x_1, y_1, s_1, \theta_1)$

$(x_2, y_2, s_2, \theta_2)$

Transform predicted by this match:

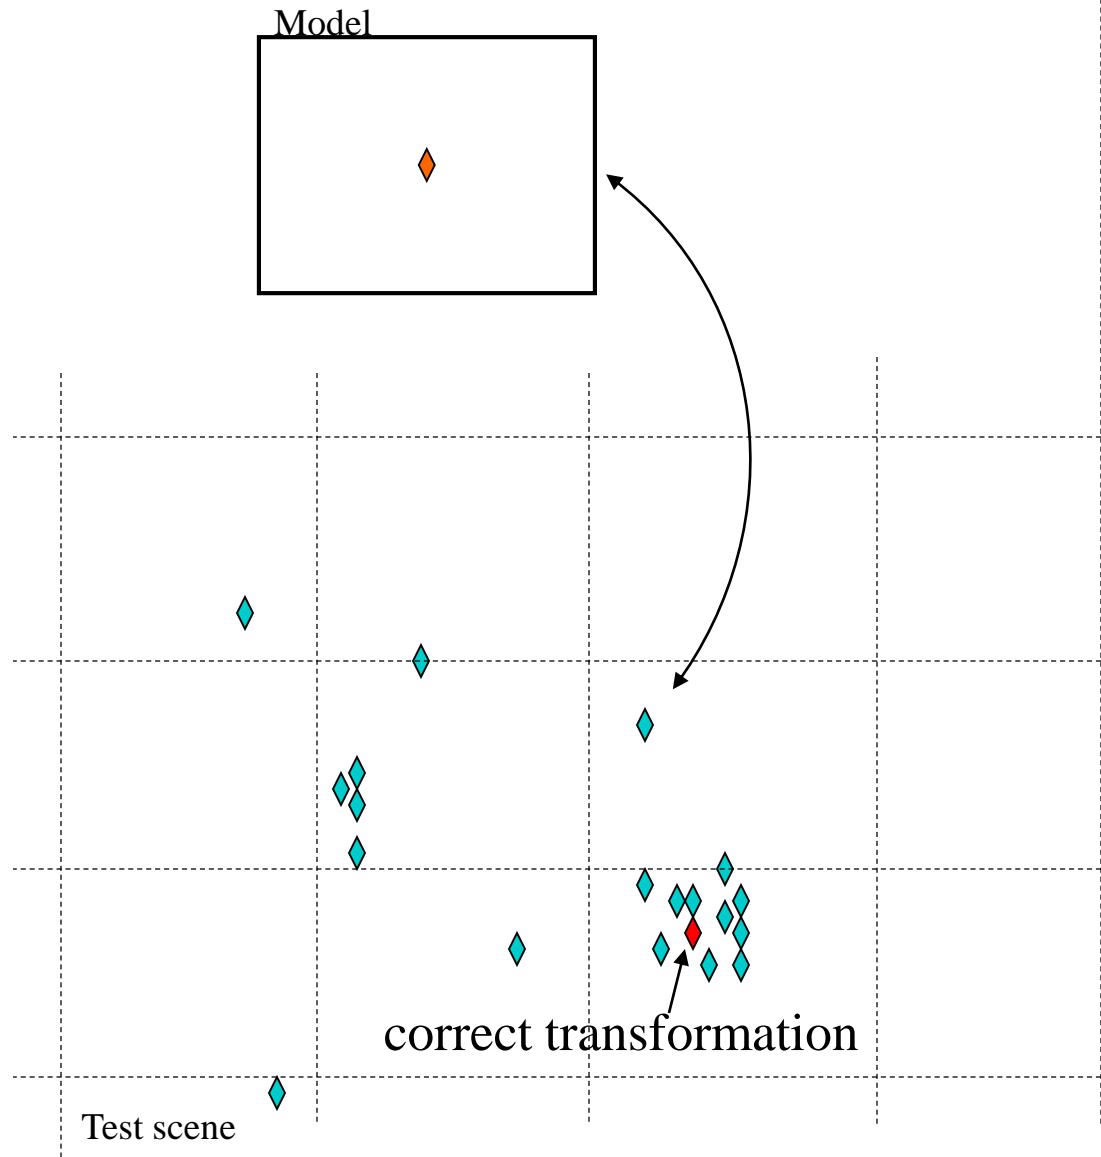

- $\Delta x = x_2 - x_1$
- $\Delta y = y_2 - y_1$
- $\Delta s = s_2 / s_1$
- $\Delta \theta = \theta_2 - \theta_1$

Each match is represented by a dot in the space of 2D similarities (Hough space)

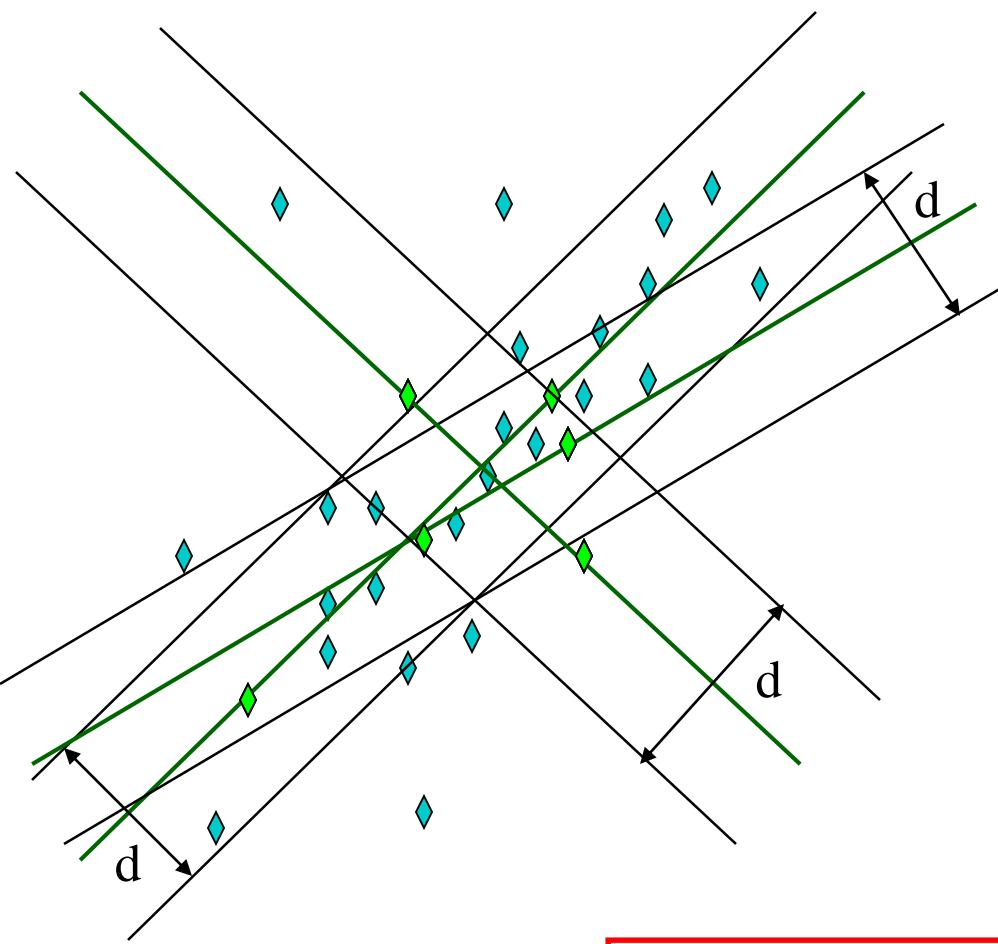

Coarse Hough transform

- Prediction of position of model center after transform
- The space of transform parameters is discretized into ‘bins’
- Coarse bins to limit boundary issues and have a low false-alarm rate for this stage
 \tilde{N}
- We count the number of votes collected by each bin.

Correspondence or clutter ? PROSAC

- Similar to RANSAC – robust statistic for parameter estimation
- Priority to candidates with good **quality** of appearance match
- 2D affine transform : 6 parameters
⇒ each sample contains 3 candidate correspondences.

Output of PROSAC : pose transformation
+ set of features correspondences

[Fischler 1973]

[Chum&Matas 2005]

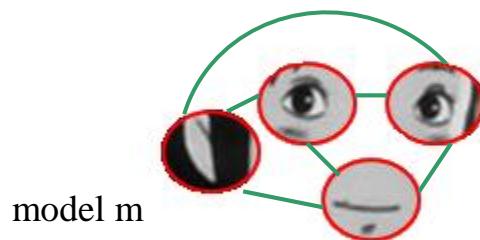

Consistency

Consistency between observations and predictions from hypothesis

$$P(F|V, \tilde{N}, \bar{N}, H, M) = \prod_{V(i) \neq 0} p_{fg}(f_i|H, f_{V(i)}) \cdot \prod_{V(i)=0} p_{bg}(f_i)$$

Common-frame approximation : parts are conditionally independent once reference position of the object is fixed. [Lowe1999, Huttenlocher90, Moreels04]

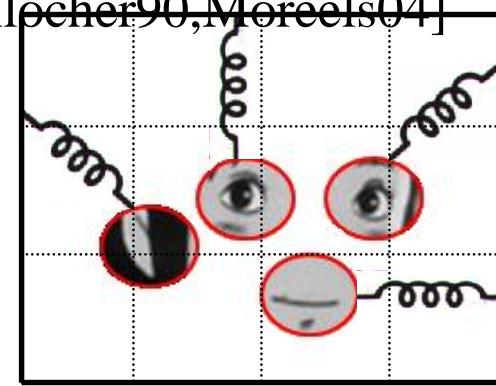

Constellation model

$$p_m(x_1 \dots x_N)$$

$$D.O.F. = O(\text{Parts}^2)$$

Common-frame

$$\prod_i p_m(x_i|\Theta_m)$$

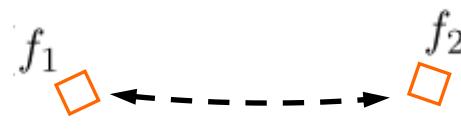

$$D.O.F. = O(\text{Parts})$$

position of
model m

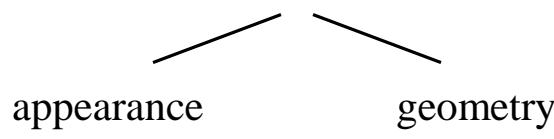

Consistency

Consistency between observations and predictions from hypothesis

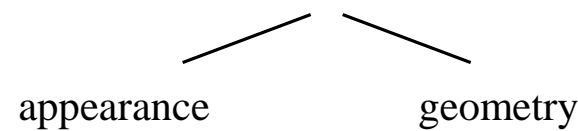

$$P(F|V, \tilde{N}, \bar{N}, H, M) = \prod_{V(i) \neq 0} p_{fg}(f_i|H, f_{V(i)}) \cdot \prod_{V(i)=0} p_{bg}(f_i)$$

foreground features

'null' assignments

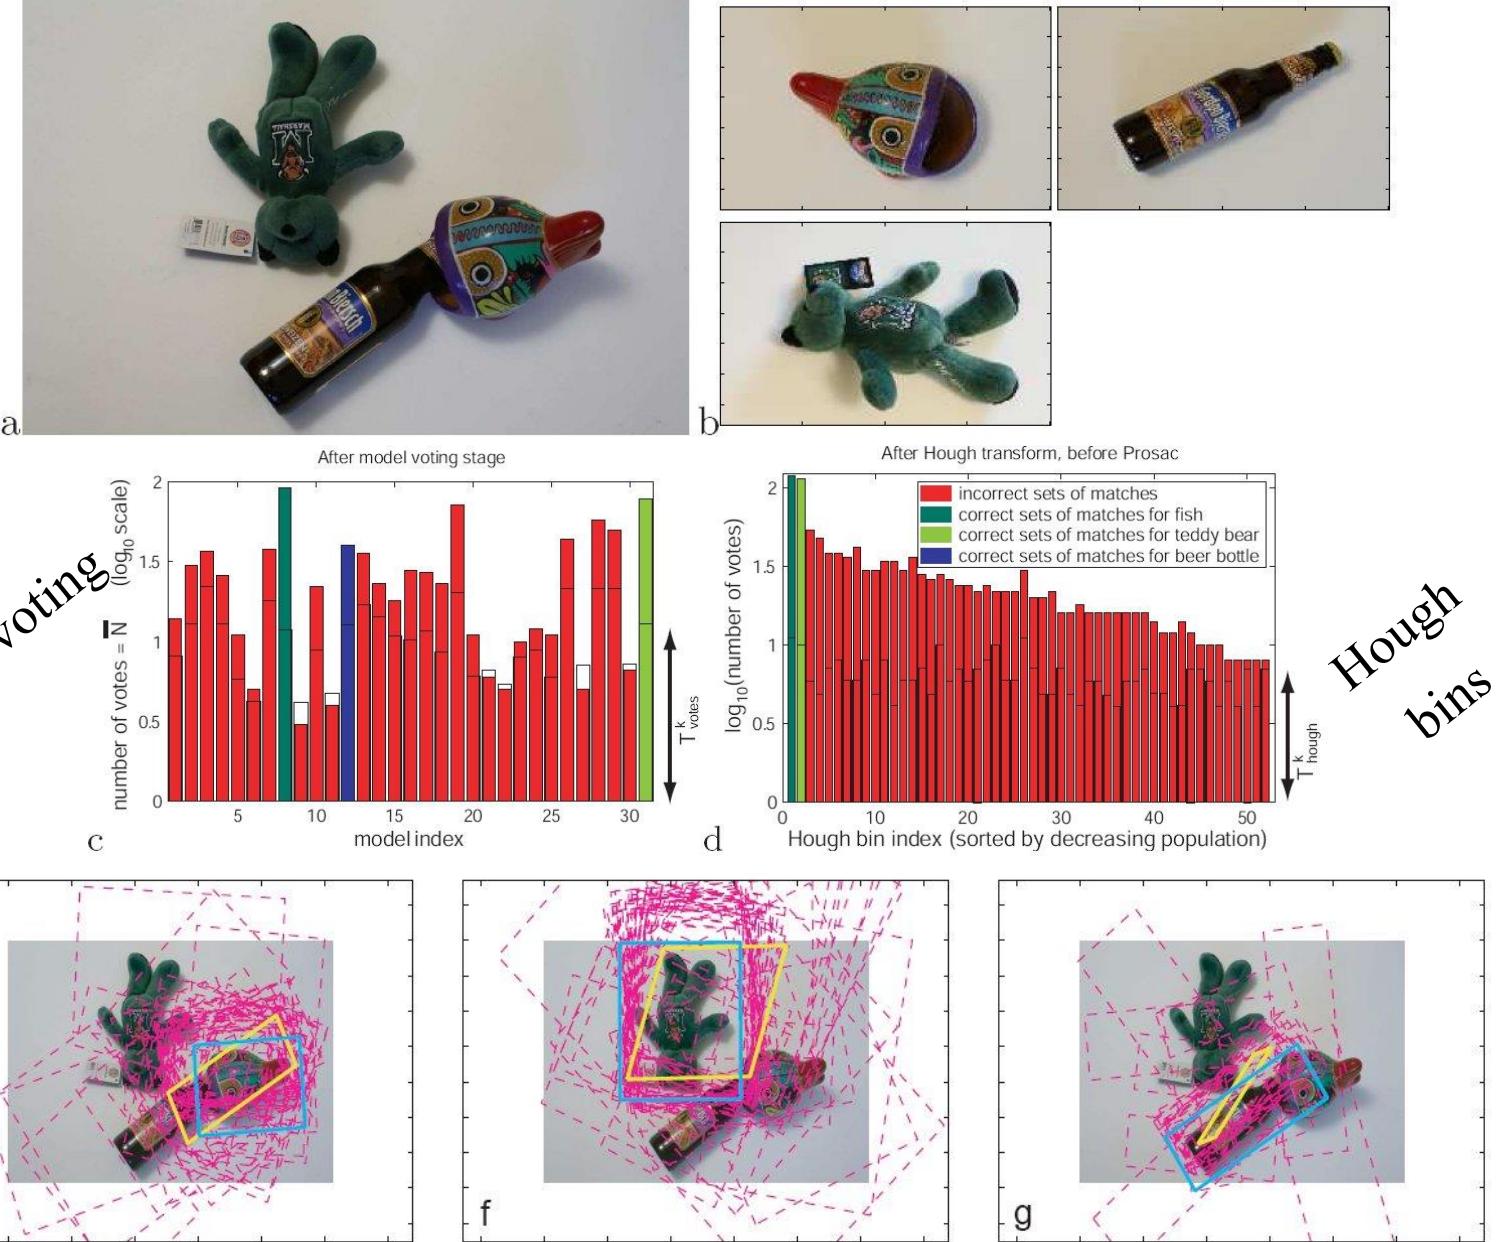

$$p_{fg}(f_i|H, f_{V(i)}) = p_{fg,\mathcal{A}}(\mathcal{A}|H, \mathcal{A}_{V(i)}) \cdot p_{fg,\mathcal{X}}(\mathcal{X}|H, \mathcal{X}_{V(i)})$$

Consistency - appearance

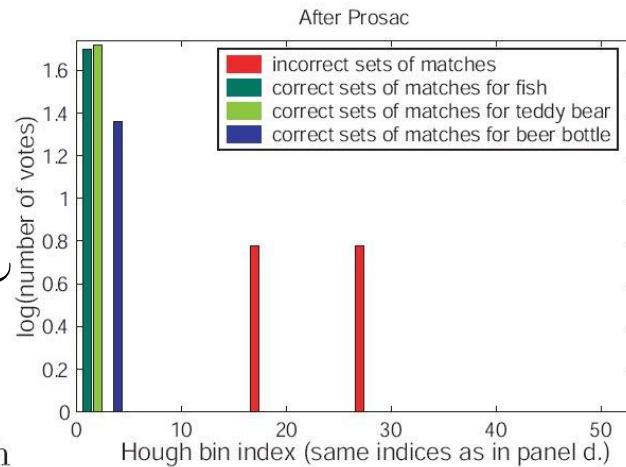

Consistency - geometry

Giuseppe Toys database – Models

61 objects, 1-2 views/object

Giuseppe Toys database – Test scenes

Test-scenes
Test-single toy
Test-no toy

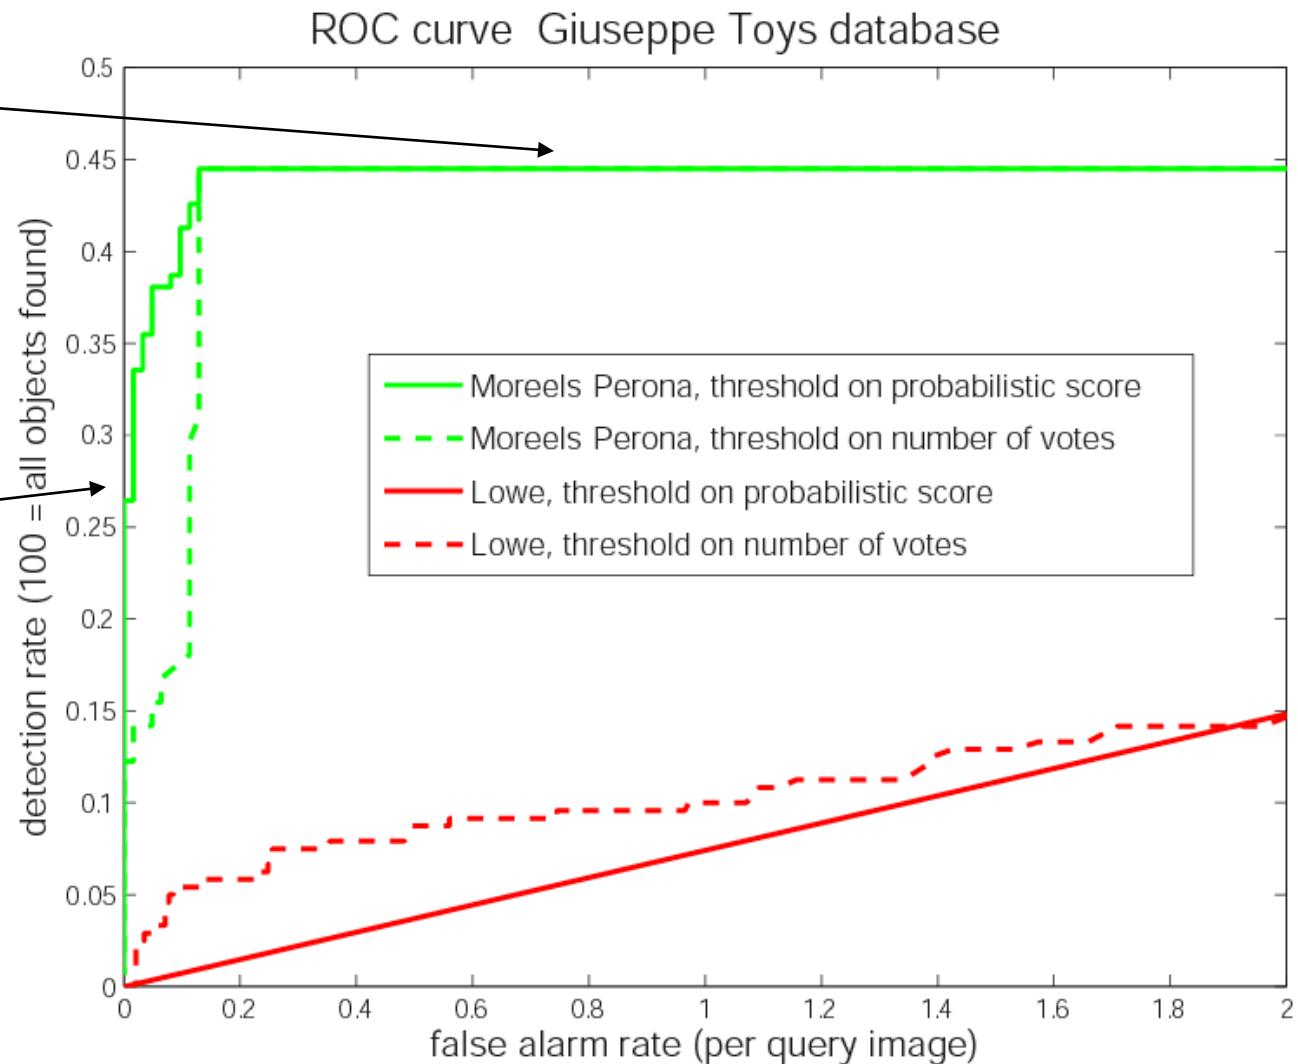

Results – Giuseppe Toys database

-
undetected objects:

features with poor
appearance distinctiveness
index to incorrect models

+
Lower false alarm
rate

- more systematic
verification of
geometry consistency
- more consistent
verification of
geometric consistency

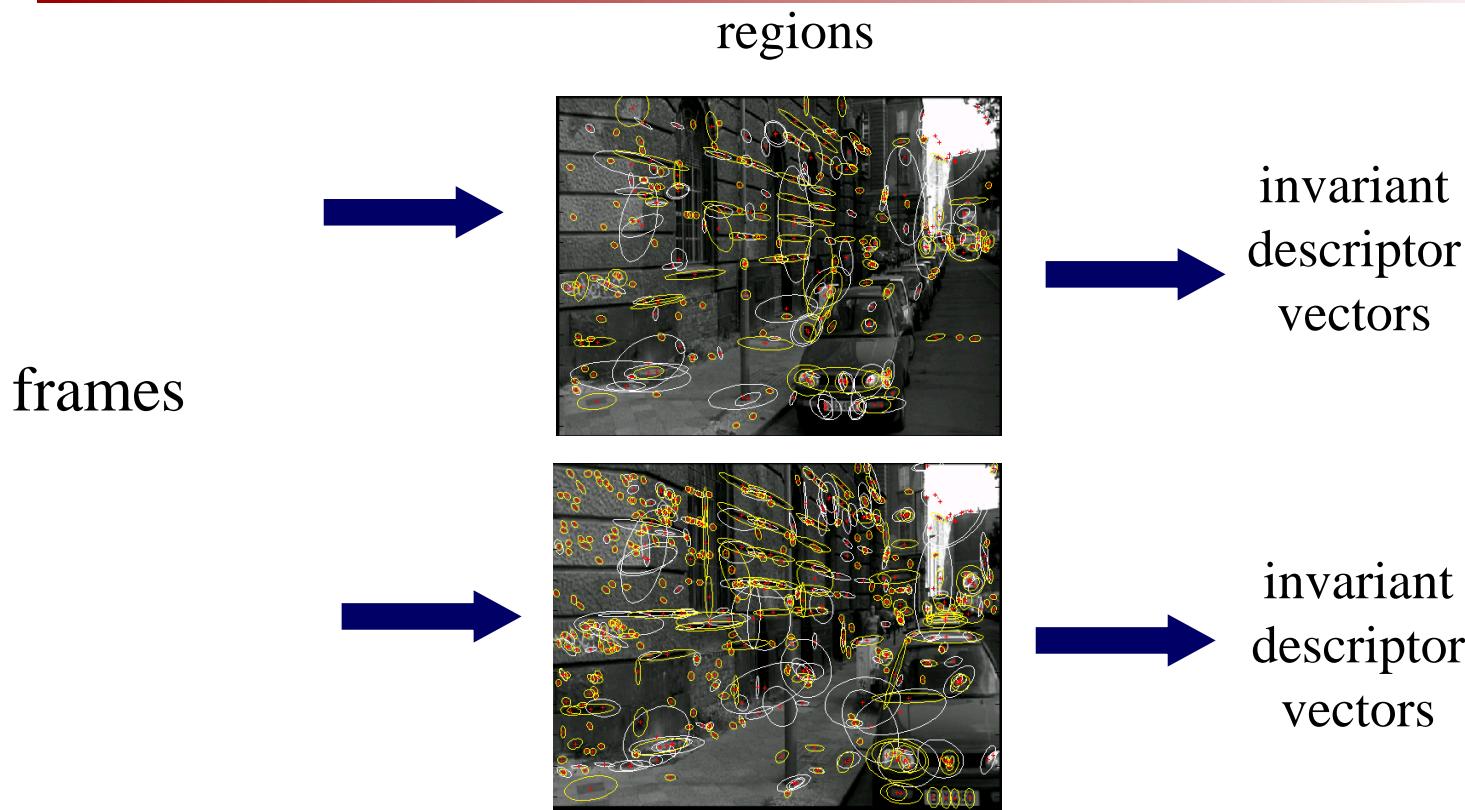

Conclusions – Moreels and Perona

- Coarse-to-fine strategy prunes irrelevant search branches at early stages.
- Probabilistic interpretation of each step.
- Higher performance than Lowe, especially in cluttered environment.
- Front end (features) needs more work for smooth or shiny surfaces.

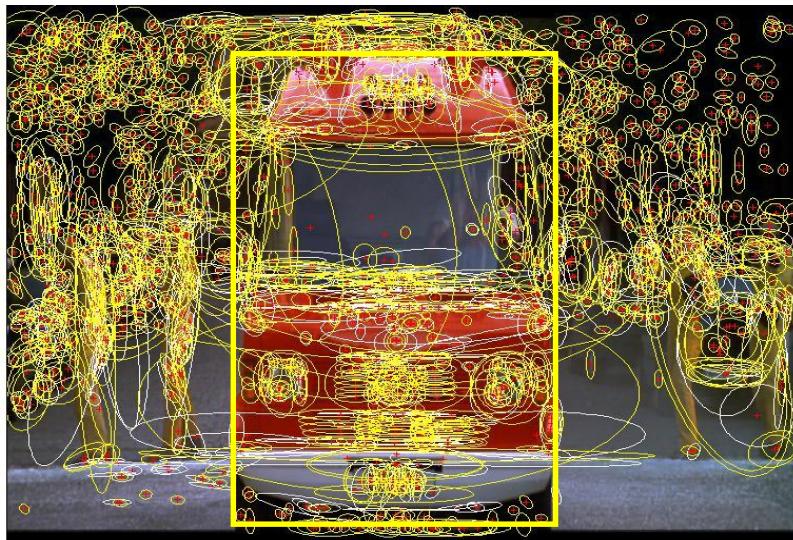

Scaling up: BOW Indexing

Outline of a large-scale retrieval strategy

1. Compute affine covariant regions in each frame independently
2. “Label” each region by a vector of descriptors based on its intensity
3. Finding corresponding regions is transformed to **finding nearest neighbour vectors**
4. Rank retrieved frames by number of corresponding regions
5. Verify retrieved frame based on spatial consistency

Example of object recognition

1000+ descriptors per frame

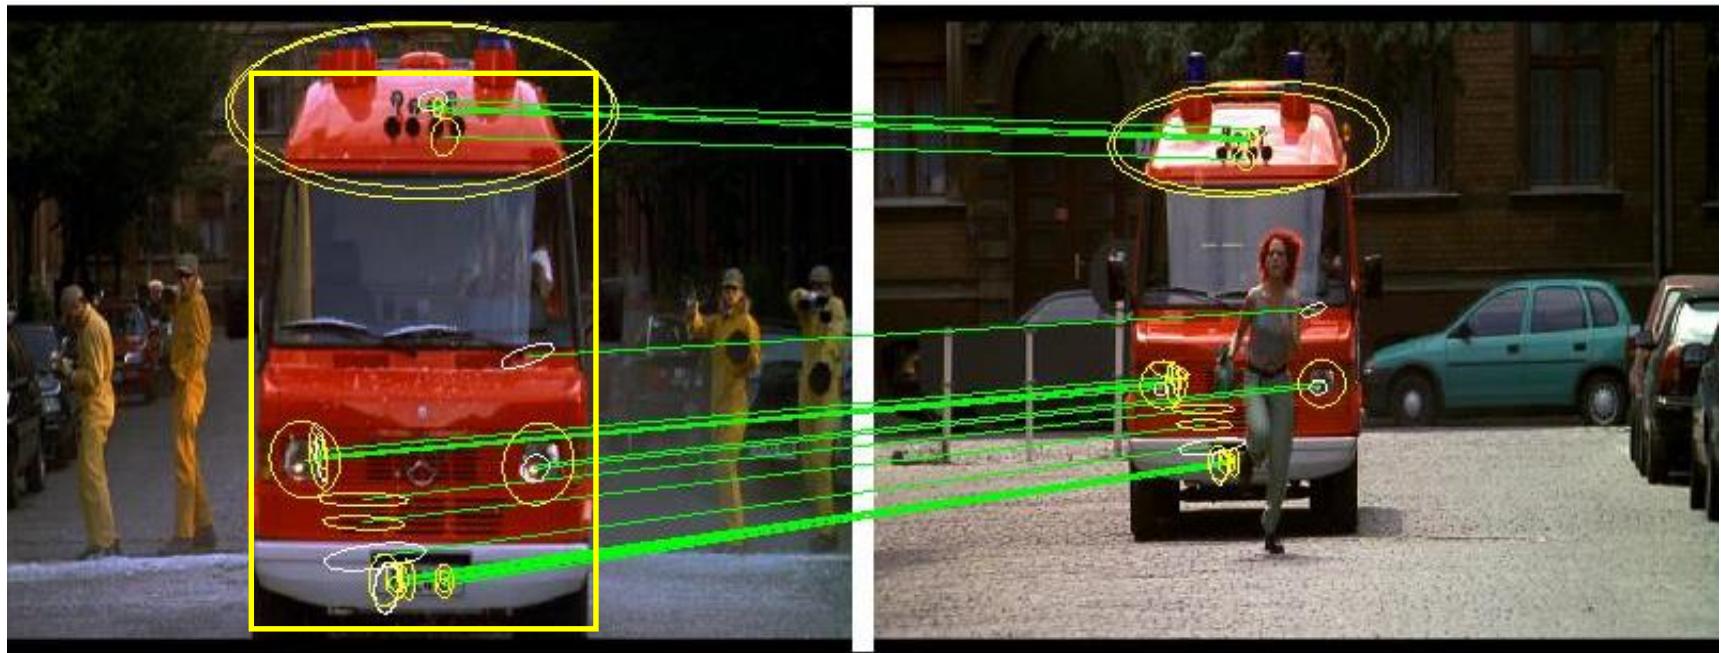

Shape adapted regions

Maximally stable regions

Slide credit: J. Sivic

Match regions between frames using SIFT descriptors and spatial consistency

Multiple regions overcome problem of partial occlusion

Shape adapted regions

Maximally stable regions

For text documents, an efficient way to find all *pages* on which a *word* occurs is to use an index...

We want to find all *images* in which a *feature* occurs.

To use this idea, we'll need to map our features to “visual words”.

Object

Bag of ‘words’

Analogy to documents

Of all the sensory impressions proceeding to the brain, the visual experiences are the dominant ones. Our perception of the world around us is based essentially on **sensory, brain, thought**, **visual, perception, cerebral cortex, eye, cell, optical nerve, image**. Through **Hubel, Wiesel**, we now know that the perception of the visual world is more complex than was once thought. By studying the visual input to the brain through various cell layers of the optic nerve, Hubel and Wiesel have been able to demonstrate that the image falling on the retina undergoes a step-wise analysis in a system of nerve cells arranged in columns. In this system each cell has its specific function and is responsible for a specific detail in the pattern of the retinal image.

**visual, perception,
retinal, cerebral cortex,
eye, cell, optical
nerve, image**

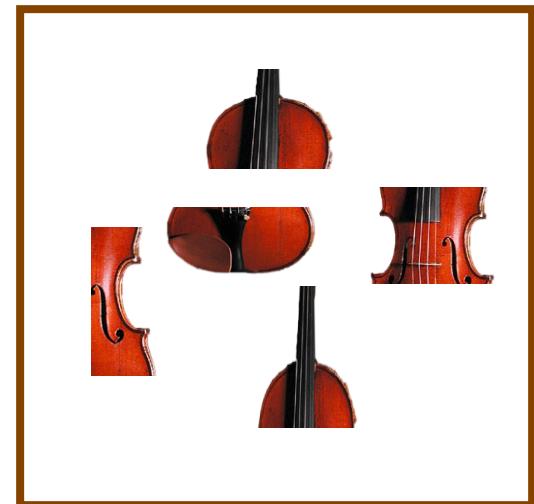

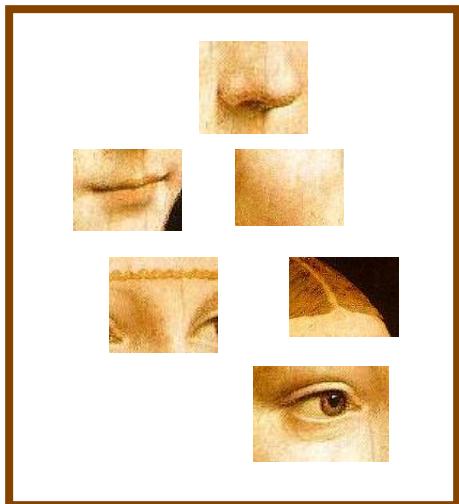

China is forecasting a trade surplus of \$90bn (£51bn) to \$100bn this year, a threefold increase on 2004's \$32bn. The Commerce Ministry said the surplus would be China, trade, surplus, commerce, exports, imports, US, yuan, bank, domestic, foreign, increase, trade, value against the dollar. the country. China has committed it to trade within a narrow band. It wants the yuan to be allowed to trade freely. However, Beijing has made it clear that it will take time and tread carefully before allowing the yuan to rise further in value.

China, trade,
surplus, commerce,
exports, imports, US,
yuan, bank, domestic,
foreign, increase,
trade, value

Stricter definition

- Independent features
- histogram representation

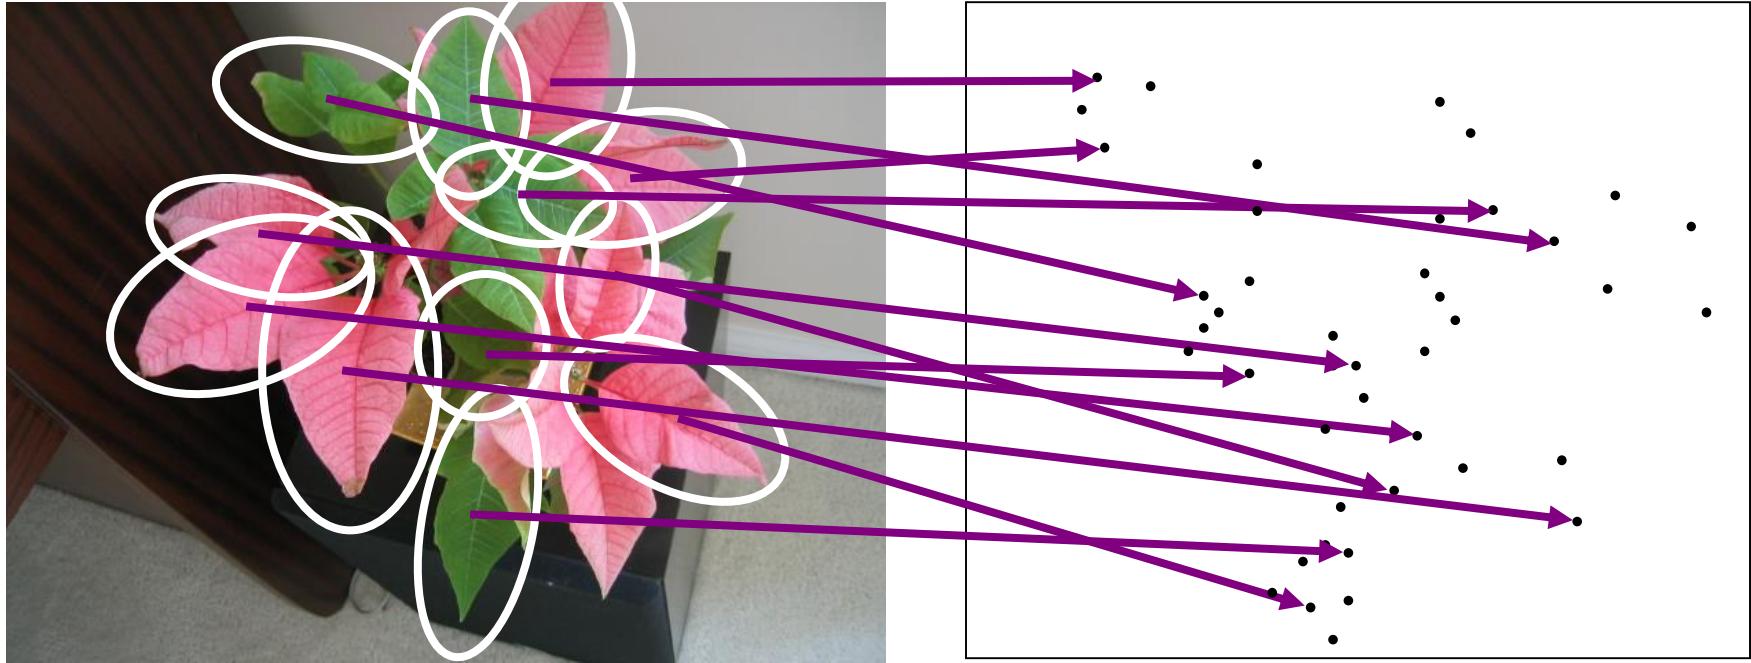

Visual words: main idea

Extract some local features from a number of images ...

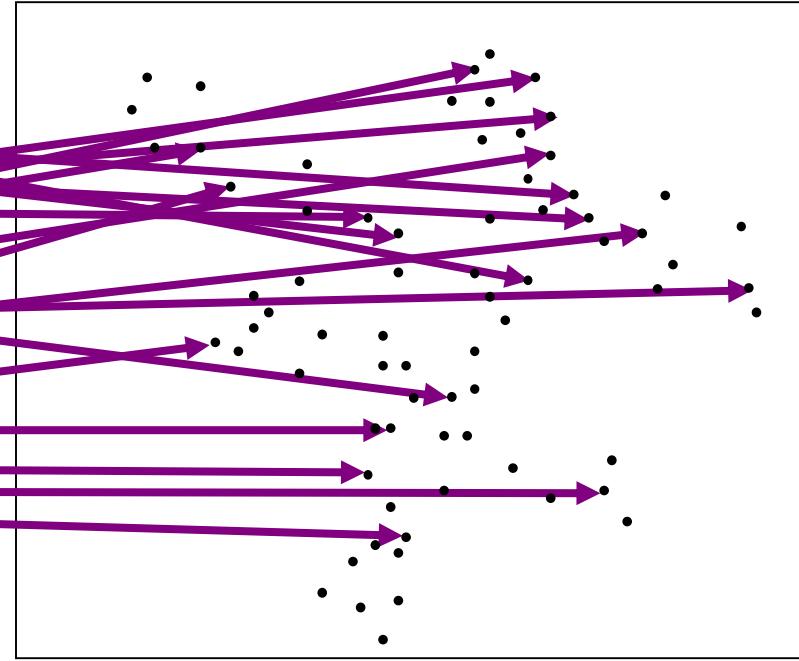

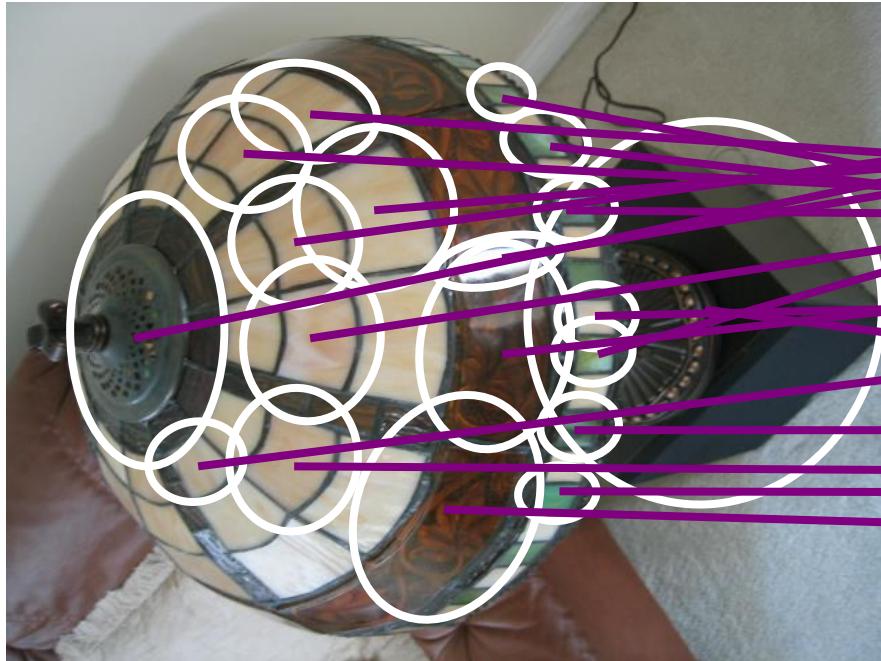

e.g., SIFT descriptor space:
each point is 128-dimensional

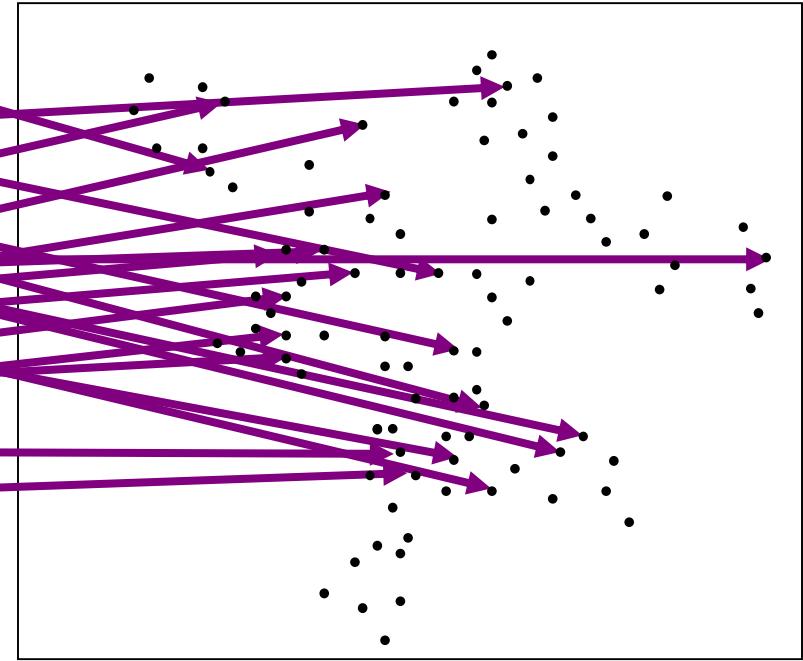

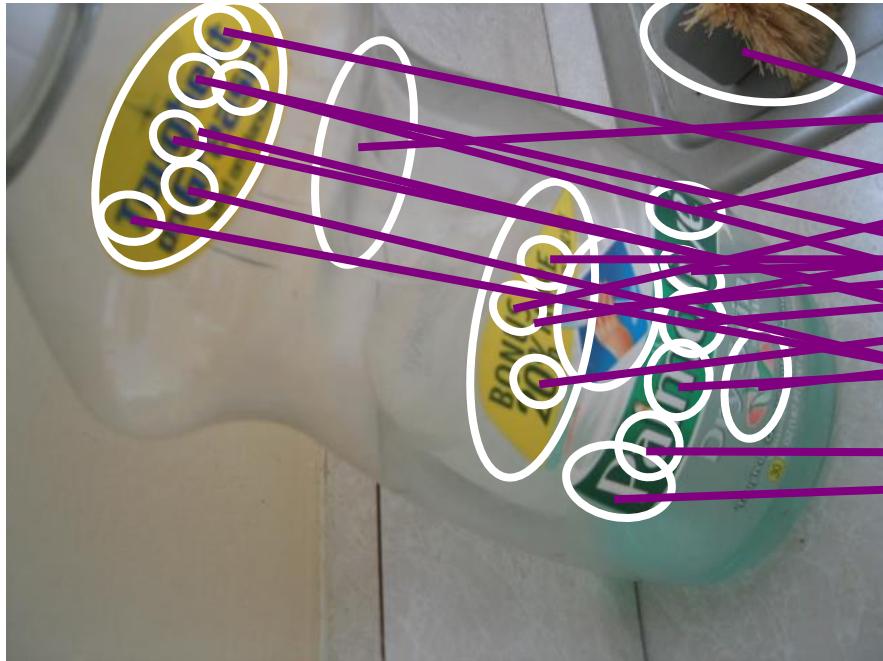

Visual words: main idea

Visual words: main idea

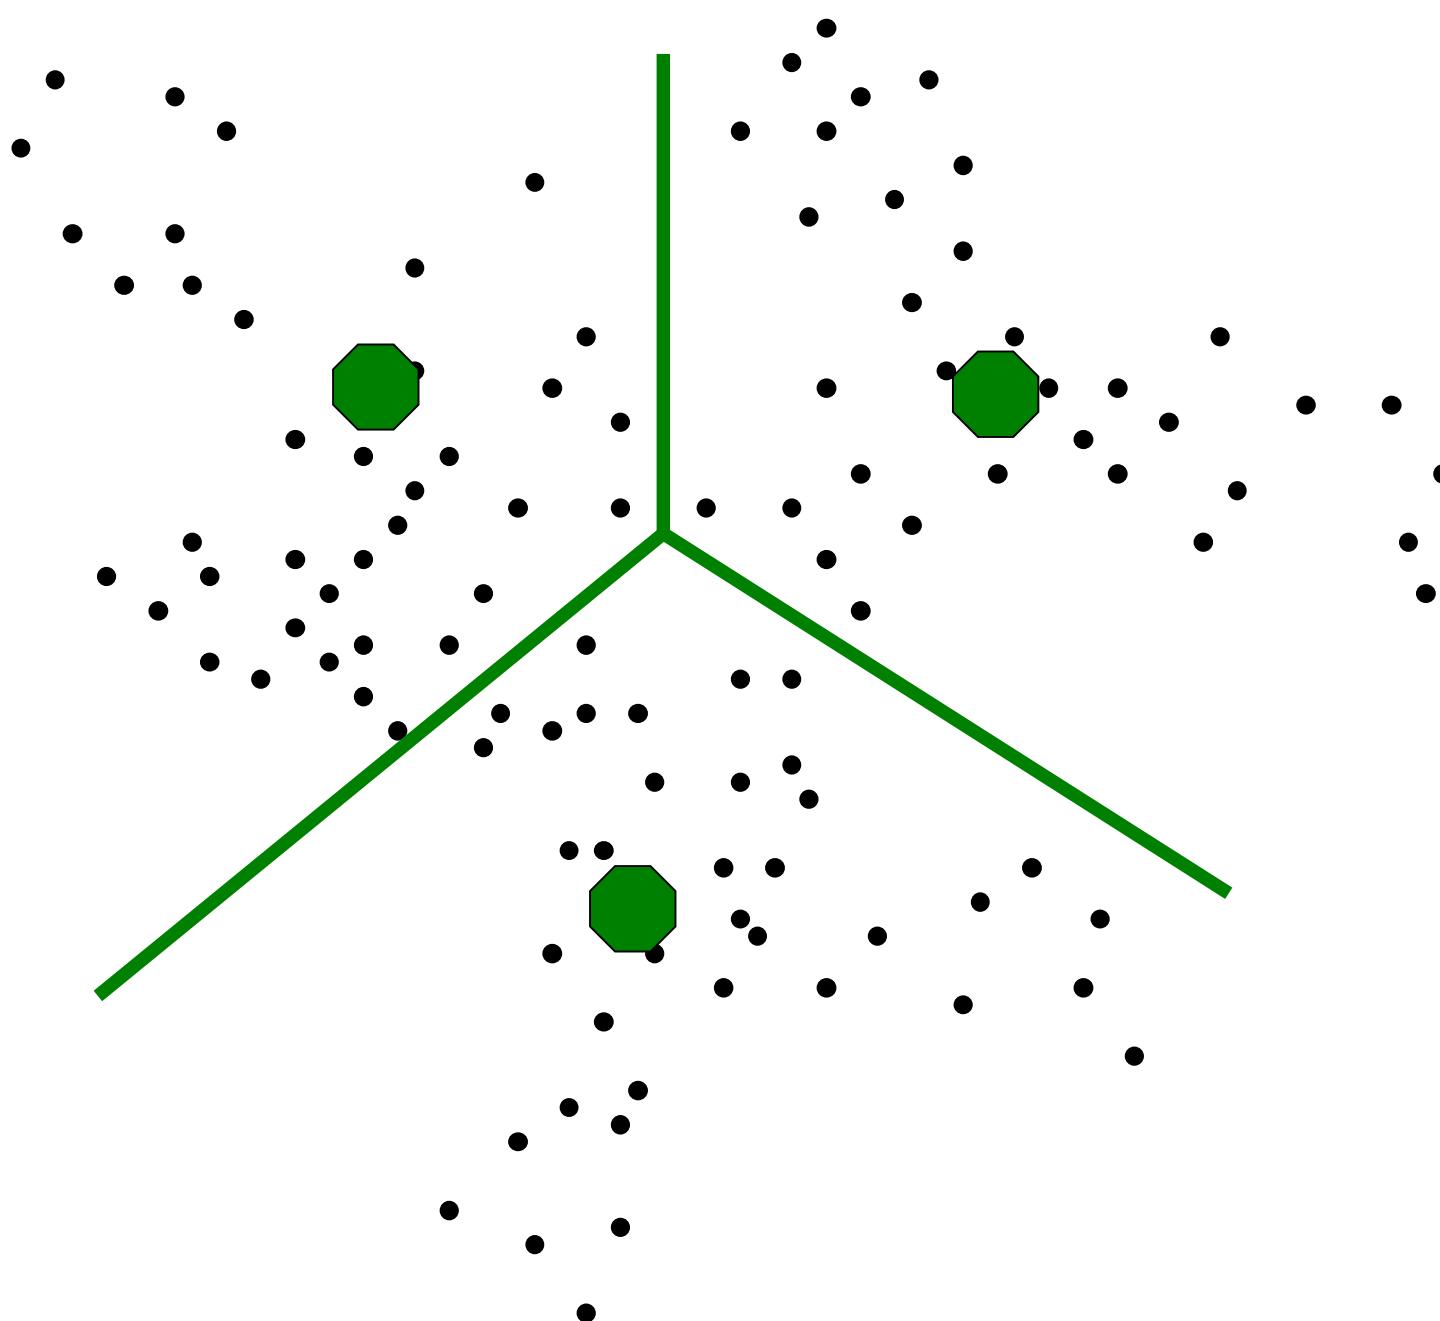

Visual words: main idea

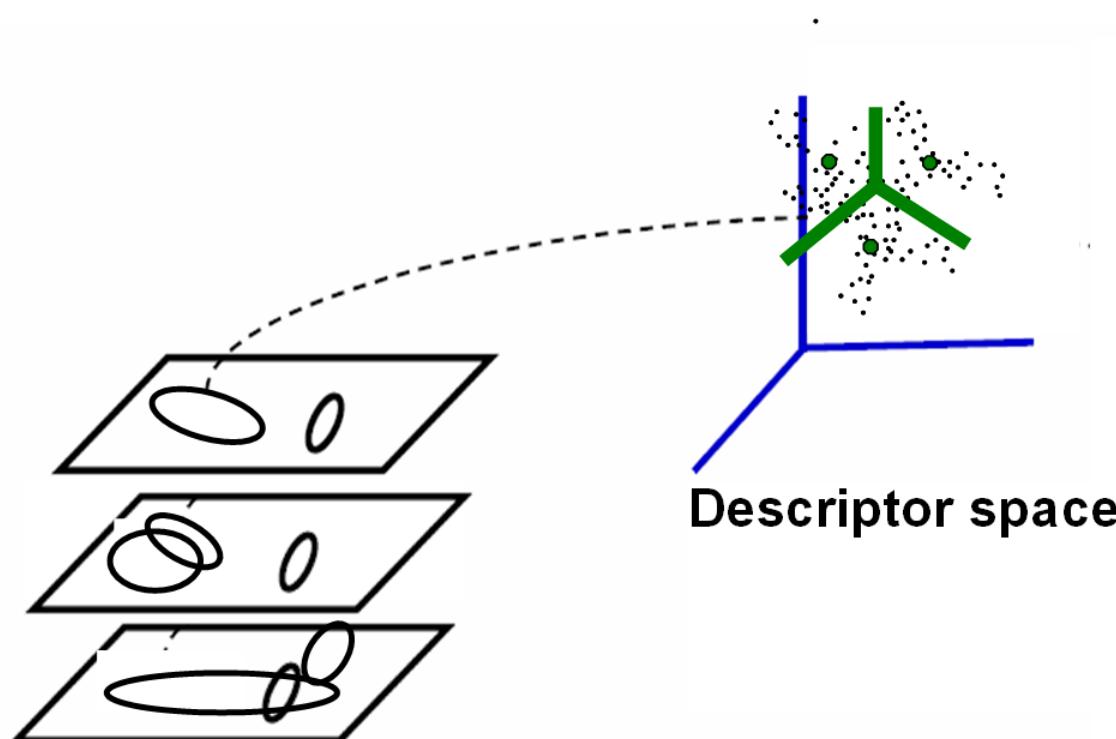

Slide credit: D. Nister

Visual words: main idea

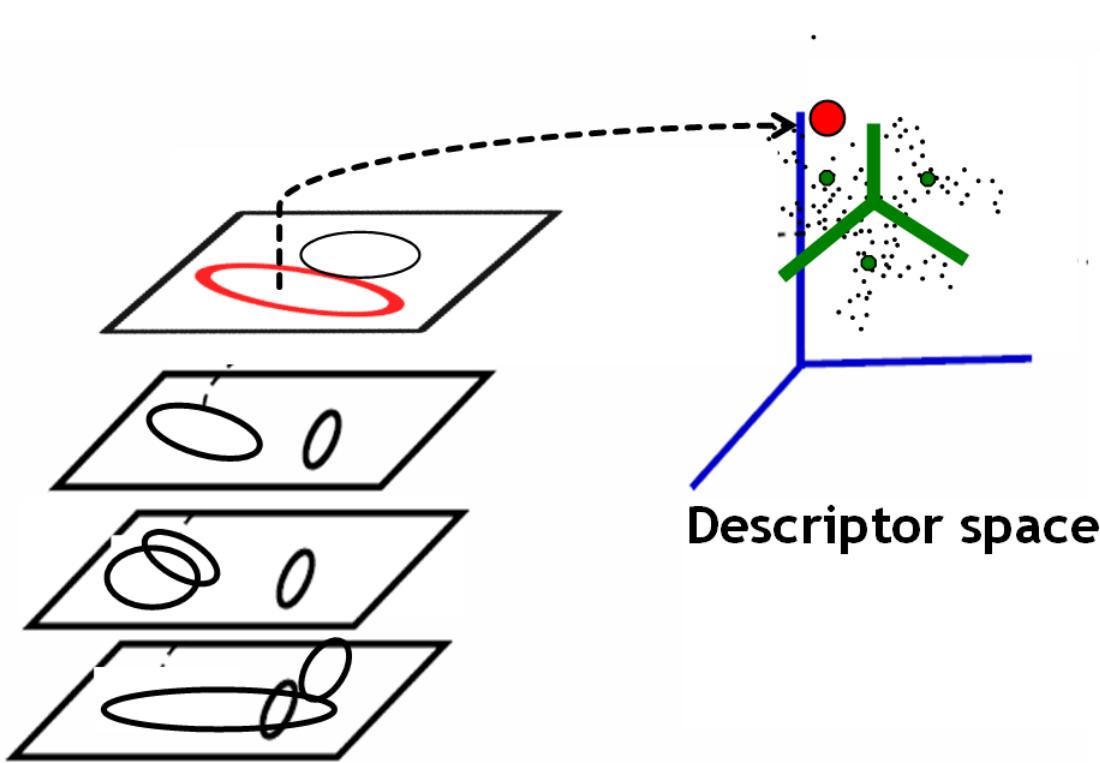

Map high-dimensional descriptors to tokens/words by quantizing the feature space

- Quantize via clustering, let cluster centers be the prototype “words”

Visual words: main idea

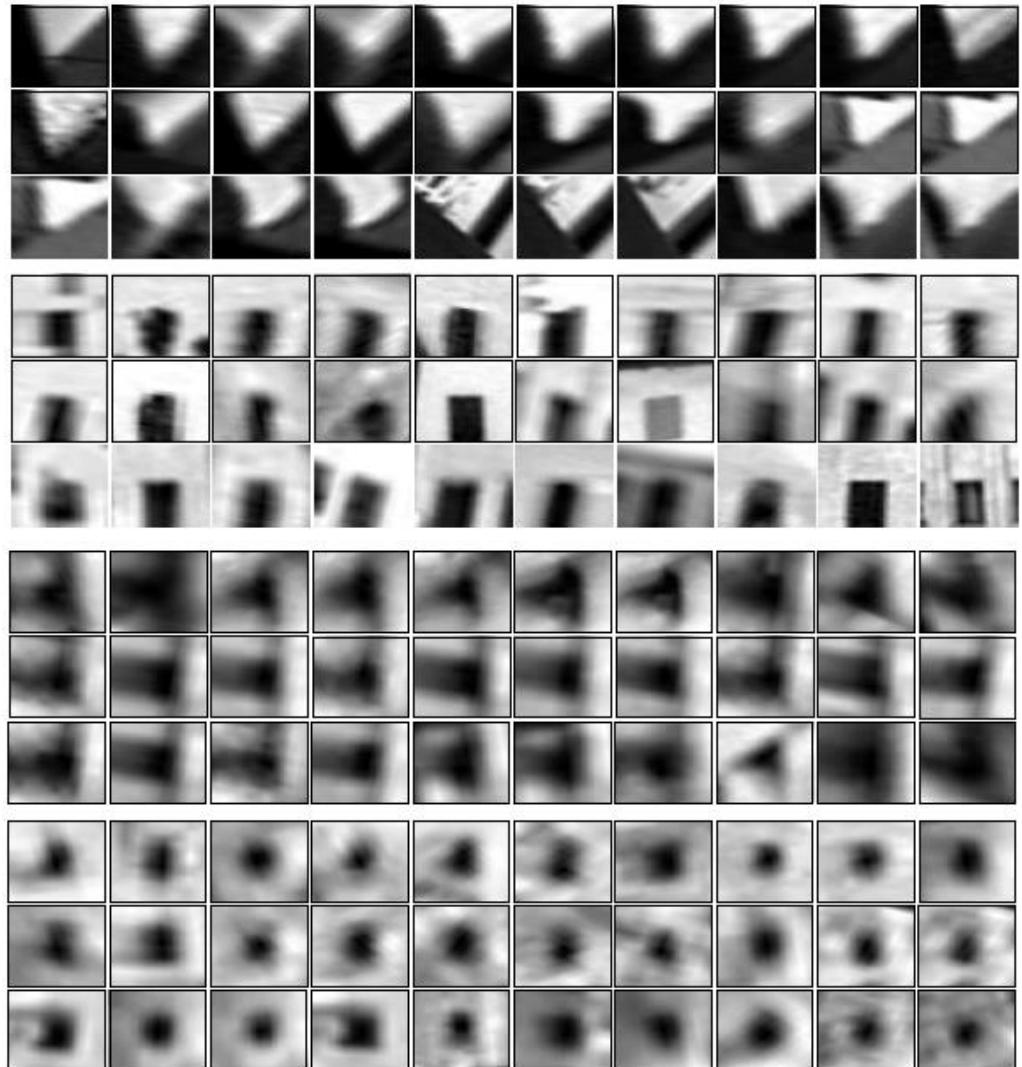

Map high-dimensional descriptors to tokens/words by quantizing the feature space

- Determine which word to assign to each new image region by finding the closest cluster center.

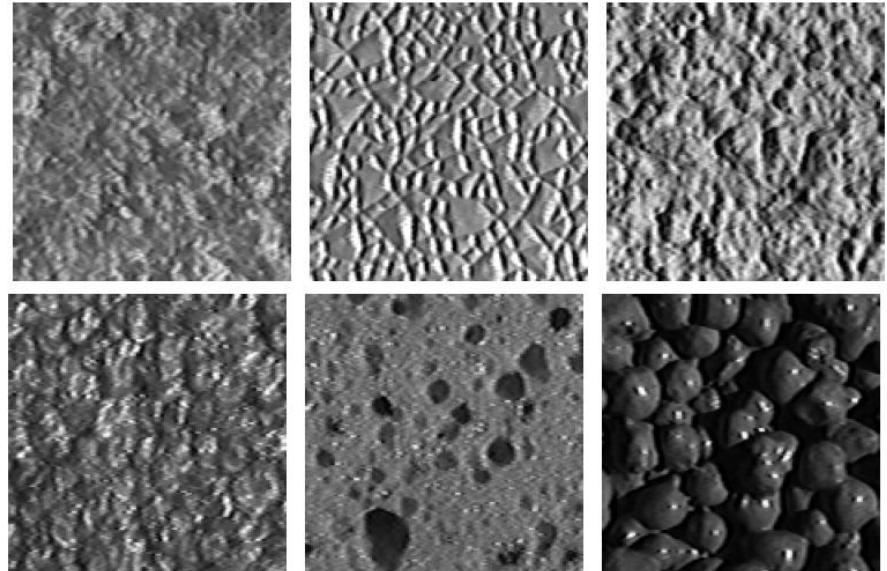

Visual words

Example: each group of patches belongs to the same visual word

Visual words

- First explored for texture and material representations
- *Texton* = cluster center of filter responses over collection of images
- Describe textures and materials based on distribution of prototypical texture elements.

Leung & Malik 1999; Varma &
Zisserman, 2002; Lazebnik,
Schmid & Ponce, 2003;

Inverted file index for images comprised of visual words

frame #5

frame #10

| Word number | List of image numbers |
|-------------|-----------------------|
| 1 | → 5, 10, ... |
| 2 | → 10, ... |
| ... | ... |

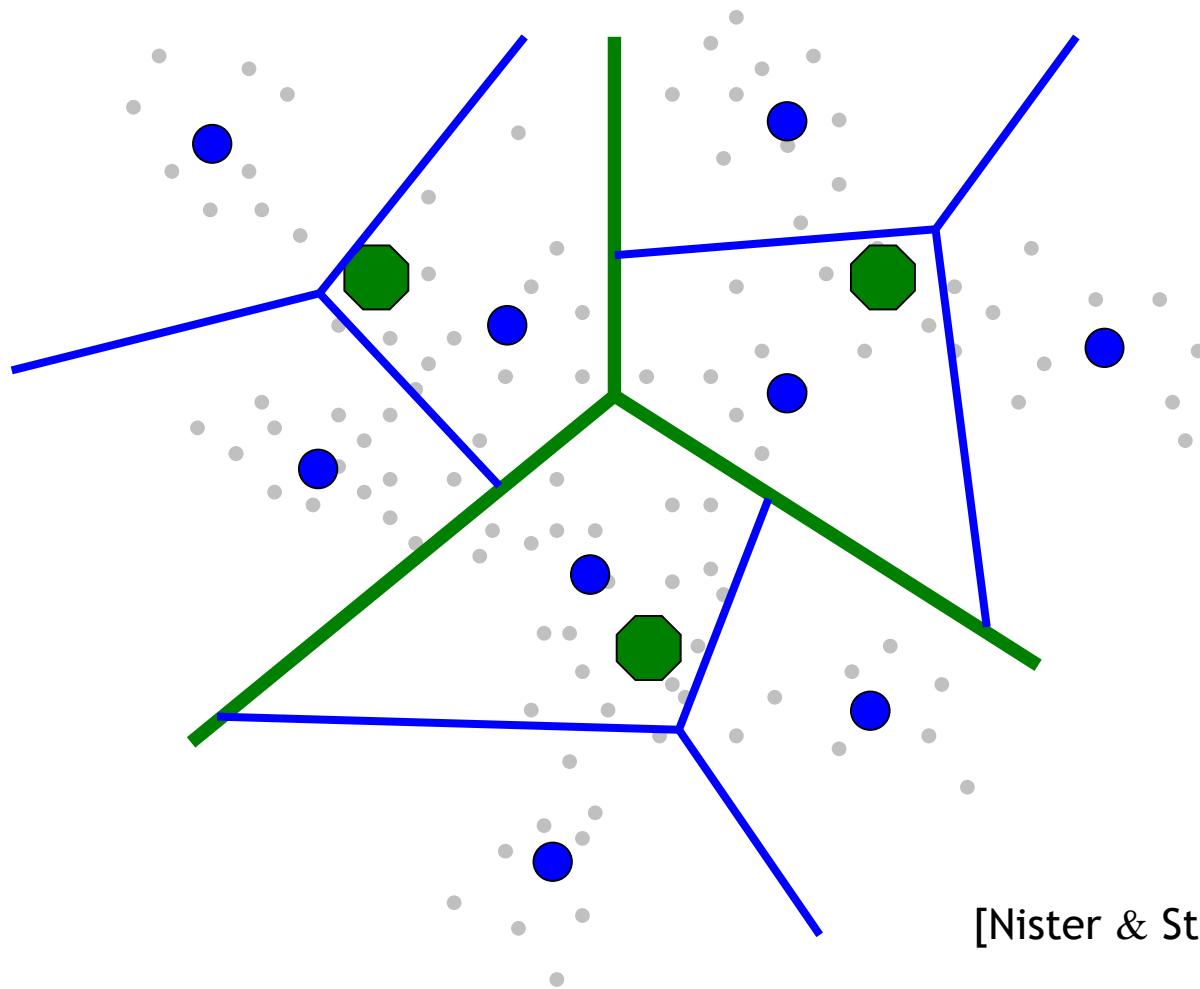

- Score each image by the number of common visual words (tentative correspondences)
- But: does not take into account spatial layout of regions

Clustering / quantization methods

- k-means (typical choice), agglomerative clustering, mean-shift,...
- **Hierarchical clustering: allows faster insertion / word assignment while still allowing large vocabularies**
 - Vocabulary tree [Nister & Stewenius, CVPR 2006]

Example: Recognition with Vocabulary Tree

Tree construction:
